**ABSTRACT**

Lipids play a nutritional physiological role by providing an efficient source of energy and essential fatty acids. As the freshwater bivalves are the filter feeder the role of mantle is very efficient. A seasonal change in endogenous and exogenous factors in freshwater bivalves requires more energy and is controlled by various ganglion such as cerebral, visceral and pedal. The lipid content in control group mussels was significantly maximym 5.9313+0.04 mg/100mg during post- monsoon and minimum during the winter season. In cerebralectomized group the content was significantly higher in unilaterally cerebralectomized mussel during the post- monsoon as compared to control, hence the present investigation was undertaken to study the impact of cerebral ganglia on lipid content in mantle of freshwater mussel *Lamellidens Corrianus*, during different season.

**Introduction**

Lipids play a nutritional physiological role by providing an efficient source of energy and essential fatty acids (Waldock and Holland 1984) the metabolism and the transport of lipids is a particular important in reproduction and larval development. (Robinson, et al. 1981).

Bivalves have been exploited worldwide for food, ornamentation and pearls throughout human history. Freshwater mussels are distributed worldwide in lotic and lentic habitats. As filter feeders, freshwater mussels are ecologically important; they control seston, recycle nutrients and provide a trophic link between primary producer and predators, (Lewandowski, et al., 1991).

Lipids are major sources of metabolic energy and essential compounds for the formation of cell and tissue membranes and they are important in the process of egg production. They also provide energy for growth during conditions of limited food supply, when carbohydrate levels are low while lipid composition and metabolism have been extensively studied in marine mollusks, a few investigations have been carried out on freshwater forms and even less on seasonal variations in the fatty acid composition of freshwater species. A detailed account of fatty acids of freshwater prosobranch mollusks from Russia, USA and India has been published. The lipid composition of the mollusks can be affected by external (exogenous) factors, such as fluctuations in the environmental conditions (temperature and food availability), or by internal (endogenous) factors, such as metabolic and physiological activities. The lipid composition of freshwater gastropods from India has been studied to some extent. The primary goals of this study were to characterize the lipid composition in the mantle of the freshwater mussel *Lamellidens corrianus*, collected from Nandrabad pond near Aurangabad. Lipid composition and metabolism have been extensively studied in marine bivalves; a few investigations have been done on freshwater forms (Pollero et al., 1981, 1983; Dembisky et al., 1992, 1993; Ekin et al., 2008) and even less on organs and tissues of freshwater species. As mentioned before, there were not much more studies on fatty acid composition of freshwater bivalve tissues. Among the known studies, only some of the freshwater bivalves *Carunculina texensis* (Hagar and Dietz, 1986), *Diplodom patagonicus* (Pollero et al., 1981), *Ligumia subsulcata* (Dietz and Graves, 1981), *Diplodondelodontus* (Pollero et al., 1983), *Dreissenapolyomorpha* and Unio sp. (Dembisky et al., 1992) and *Dreissena siouffi* (Ekin et al., 2008) have been reported, but very little attention is given on the role of cerebral ganglia in regulating the lipid metabolism hence the present investigation has been undertaken to study the impact of removal of cerebral ganglia unilaterally and bilaterally in lipid content in mantle in freshwater bivalve mussel *Lamellidens Corrianus* during different season.

**Material Method:**

The freshwater bivalve molluscs, *Lamellidens corrianus* inhabits in the Nandrabad pond situated in Khultabad taluka 19km away from Aurangabad. During summer, monsoon, post- monsoon and winter season the collection of 15 individuals of the shell length 95-110 mm were selected and were acclimatized to laboratory condition for 24h. Surgical operations were performed so as to remove cerebral ganglia unilaterally and bilaterally within 30 seconds after lapse of 2 to 3 hours in the laboratory condition. The animals were divided into 3 groups non-operated served as control and other two were experimental. In each group 5 animals were selected and after lapse of 7 days the animals were sacrificed and the mantle, were dissected and dried in the oven to prepare the powder for estimation of lipids using standard method Vanillin reagent method of Barnes et al. [1973]. The value of estimate was subjected to statistical analysis.

**Estimation of lipid:**

The total Lipid was estimated by the vanillin reagent method of Barnes et al. [1973].

The quantitative determination of lipid by sulphophosphovanillin method depends on the reaction of lipids (extracted from the sample using chloroform: methanol) with sulphuric acid, phosphoric acid and vanillin to give a red colour complex.
Reagents:
Chloroform: Methanol [2:1 v/v]
Conc. Sulphuric acid,
Orthophosphoric acid.
Vanillin Reagent: 2 gm vanillin in 200 ml H2O. Add 800 ml Orthophosphoric acid. Keep in dark bottle for 15 to 20 days before use.

Procedure:
100 mg tissue was homogenized by adding 10 ml of chloroform: methanol (2:1) mixture. The homogenate was filtered and 1 ml of this filtrate was kept at room temperature in laboratory at 37 °C for 2 days. 1 ml of concentrated sulphuric acid was added to dry mixture and kept in boiling water bath for exactly 10 minutes, followed by rapid cooling under tap water. 0.2 ml of this solution was then and 5 ml vanillin reagent was added and kept aside for 30 minutes at room temperature (37 °C). The optical density was read at 530 nm using UV-VIS Spectrophotometer.

Cholesterol was used as a standard. Lipid content was calculated with the help of standard graph and expressed as mg / 100 mg wet tissue.

Results and discussion:
Lipid contents were determined in dry samples of mantle, in each individual. The results of the experiments were shown in Table. 1.and Fig.1. The physico-chemical parameters of the water used in the experiments during different season were also studied temperature was in between 33°C to 22°C; pH 7.4 to 7.6; hardness 240to 100 mg/L and oxygen content 4.40 to 9.67mg/L / h. Impacts of cerebralectomy were studied to determine the biochemical lipid content in mantle of freshwater bivalve mussel, Lamellidens corrianus. The mussel mantle were analyzed to observe the effect of cerebralectomy unilaterally and bilaterally respectively. The data were exposed to various statically analysis. Student ‘t’ test was used to find out significance. The level of significance was used in the present study (p<0.001, p<0.01 and p<0.05).

Lipids: In the mantle of control mussel, the Lipid level was observed in post- monsoon was showed a significant decrease 5.93± 0.04 as compared to experimental mussel. In unilateral group mussel the content was 6.14 ± 0.04 and in bilaterally cerebralectomized mussel the mantle content was 4.66± 0.09 respectively .

In Monsoon the mantle content in control mussel was shown an increase level in lipids 2.07 ± 0.04 as compared to summer season. In experimental mussel the Lipids level showed a significant (p<0.001) decrease 1.19± 0.04 in unilaterally cerebralectomized mussel by 55.55% a significant (p<0.001) decreased in bilaterally cerebralectomized mussel1.19± 0.04 by 110.56%.

In post monsoon the Lipids content was again showed a significant decrease 5.93 ± 0.09by 14.33% in control mussel. In experimental mussel the Lipids content was significantly increased 6.14± 0.04 and 6.64 ± 0.09 by 77.77% and 18.71 % ( p<0.001) .Where as the lipids content was maximum in post- monsoon season in control mussel as compared to other seasons.

In winter season the lipid content in control group was 1.20 ± 0.09(22.80 %) and in experimental group mussel were 1.07 ± 0.004 (88.30%) and 1.09 ± 0.009 (94.66%) a significant increase was observed as to control animals.

Lipid is an important dietary constituent, serve as reserve energy when food supply is scanty. In stressful environmental conditions, after glycogen lipid is use as energy source (Shigmates and Takeshita, 1959). In the present study the lipid content decline in winter indicate that at the time of fully maturity of gonads the other biochemical content increased and lipid content lower and increased in post- monsoon due to the ripening and matured released of gametes.

Lipid composition and storage strategy in molluscs, particularly of bivalves and gastropods have been studied since lipids constitute a major fraction of molluscan tissues (Voogt, 1983). Almost concern the entire organism and only a few reports on the tissue distribution of fatty acids are available (Hagar and Dietz, 1986; Wenne and Polak, 1989). Seasonal variations in lipid and fatty acid compositions have been reported for several marine bivalve molluscs, including Pecten maximus, Crassostrea gigas, Tapes decussatus, Tapesphilippinarum, Scapharea inaequilivulis (Beninger and Stephan, 1985; Piretti et al., 1988; Pazos et al.,1996, 2003). Some of the other studies on bivalve fatty acids were concerned with analyses of whole animal (Watanabe and Ackman, 1974; Trider and Castell, 1980; Misra et al., 1985; Alkanani et al.,2007; Ekin et al., 2008). Furthermore, analyses on fatty acid composition of tissues were usually related to seasonal variations, sexual development and growth metabolism of marine bivalves, a few investigations have been done on freshwater forms (Pollero et al., 1981, 1983; Dembtsky et al., 1992,1993; Ekin et al., 2008) and even less on organs and tissues of freshwater species. As mentioned before, there were not much more studies on fatty acid or lipid content composition of freshwater bivalve tissues. Among the known studies, only some of the freshwater bivalves, Carcinulina texasensis (Hagar and Dietz, 1986), Diplodom patagonicus (Pollero et al., 1981), Ligumiasubrostrata (Dietz and Graves, 1981/Diplodonodolodontus (Pollero et al., 1983), Dreissenapolymorpho and Unio sp. (Dembtsky et al., 1992) and Dreissena sioiffi (Ekin et al., 2008) have been reported, but very few literature is available on impact of cerebralectomy, hence the study was undertaken, thus it might be concluded that the impact of removal of cerebral ganglia unilaterally and bilaterally has an inhibitory effect in lipid content metabolism.
