ABSTRACT
The partial substitution of the ureter using a pediculated double short segments of the ileum is a technique used to re-establish ureteral transit and preserve the renal unit, following the resection of extensive ureteral lesions. Standard surgical procedure for an ileoureteroplasty consists of isolating an ileal duct of equal or greater length than the ureteral defect and interposing it in the urinary tract in an isoperistaltic direction. Monti described a surgical technique that allows for the creation of catheterizable stomas in continent urinary diversions, using the Mitrofanoff principle. These passageways were created from one or several 2.5 cm long ileal sections by means of their detubulization and transverse retubulization.

Introduction
Long ureteric defects may occur as a result of iatrogenic ureteral injuries, recurrent pelvi-ureteric junction obstruction, chronic inflammatory diseases such as tuberculosis, retroperitoneal fibrosis and ureteral carcinoma. Several techniques were described to compensate this defect by intrinsic urinary tissue such as direct anastomosis, psoas hitch, Boari flap, transuretero-ureterostomy and renal autotransplantation.

In some occasions the ureteral defect is too long to the degree that extra urinary tissue is needed to overcome it. Accordingly, other alternatives have been tried such as artificial ureteral substitutes e.g. Gore-Tex tube graft (1) which showed disappointing results in contrast to the promising ones that were achieved with the use of pedicled bowel grafts (2). The most commonly used technique is that of ileal ureter replacement which was first described by Schoemaker in 1906 (3) and gained wide acceptance later on.

One of the modifications of this technique was the application of Yang-Monti principle (4,5) which allowed the creation of a long tube from short bowel segment after its reconfiguration. It was applied for ureteral replacement first in dogs (6) then clinically (7) in few reports.

Observation
A 54 year old man with a desmoid tumor right story, recently diagnosed by computed tomographic examination (Figure 1) for the occurrence of multiple right renal calic. Physical examination was unremarkable. Renal function was normal and urine culture was negative. Initially, a double J stent was performed to compensate for the right urétérohy dronéphrosis. Three months later, surgical removal by median laparotomy was performed. A long portion of the ilioolumbar ureter was sclerotic, so we decided to make a ureteral replacement.

Technique
Isolation of 5 - 7 cm of the terminal ileum on their vascular border. Then, according to the Yang-Monti principle, the isolated ileal segment was further subdivided into 2 equal parts (each 2.5 cm in length) with preservation of the individual blood supply (Figure 2). The continuity of the ileum was reestablished. Each ileal segment was incised at its longitudinal axis close to the mesenteric border.

Unfolding of the incised segments with suturing of their adjacent ends were performed and resulted in the formation of an intestinal plate 2.5 cm wide and 10-12 cm. This plate was tubularized around 16F Nelaton catheter using 4/0 absorbable sutures (Figure 3). Then we realized a spatulisation both proximal and distal ends of the ileum, before establishing a uretero-ileal anastomosis without tension and using two hemi-running 3/0 absorbable sutures. A double J protection stent will be kept for 4 weeks.

Discussion
Nowadays, iatrogenic ureteral trauma showed an increased incidence as one of the causes of ureteric stricture (8,9). This could occur as a result of direct injury or focal ischemia to the ureter (10).

Ileal ureter replacement became now an established procedure for ureteric reconstruction especially after the urologists gained more experience in bowel surgery (11). Several studies reported encouraging results regarding surgical outcome and renal function (2,9), however common drawbacks were reported mostly attributed to the absorbing and secreting criteria of the involved ileal segment such as hyperchloremic metabolic acidosis and excess mucus production and also to the wide caliber refluxing ileal ureter with subsequent progressive dilatation, functional obstruction and recurrent urinary tract infections (9,12). So, to overcome these complications and to improve the surgical outcome, the Yang-Monti principle was applied as a modification of original simple ileal ureter replacement, which allowed the reconstruction of long tube from a reconfigured short bowel segment.

Intraoperatively, we used 2 ileal segments. Each ileal segment provided a tube of about 6 cm length after

reconfiguration. We found that this technique is safe as it was not associated with mortality or significant morbidity.

UIV showed improvement of split renal function without urinary obstruction (figure 4) so we found that ileoureteral anastomosis can be done successfully with no worry about organic or functional obstruction in carefully selected cases.

During follow-up, no complaint of excess mucus production was observed which was also noticed by other authors that used the same procedure (7). This observation is considered an advantage of this modification and most probably due to the marked reduction in the size of the secreting surface area in comparison to simple ileal ureter that may be associated with mucus obstruction in some cases (12). Moreover, hyperchloremic metabolic acidosis did not occur in our case, however it was reported by various studies using simple ileal ureter in varying percentages (8,9). Absence of metabolic disorders among our case can be explained by proper selection of patient (serum creatinine = 12 mg/l) and reduction of the size of absorbing surface area.
