Development of sustainable concrete by using paper industry waste

Kiran Kumar Poloju*, Dr.Ram Kishore Manchiryal and Chiranjeevi Rahul R
Department of Civil Engineering, Middle East College, Muscat, Oman.

1.1 Introduction

While the developed, industrialized countries are called upon to reduce pollution of the environment and their share of the usage of the world’s resources, including energy, the developing countries need to avoid the mistakes of the past. This problem is particularly acute, since cement production as well as fly ash generation in developing countries are expected to increase significantly in the next few decades. There is an increasing demand for concrete worldwide, estimated to double within the next 30 years. This demand can be met without a corresponding increase in greenhouse gases by using supplementary cementitious materials to replace a maximum amount of the cement in concrete; we can reduce energy and resource consumption, reduce CO₂ emissions, and reduce the negative environmental impact. There is a further environmental benefit in that most commonly used supplementary cementitious materials (SCM) such as Lime sludge, fly ash, silica fume etc. are some different kind of waste products and end up in landfills. Paper making generally produces a large amount of solid waste. It means that the broken, low-quality paper fibers are separated out to become waste sludge. This paper mill sludge consumes a large percentage of local landfill space every year and also contributes to serious air pollution problems. It is most essential to develop profitable building materials from them. This report concisely explains the technical and environmental benefits of supplementary cementitious materials use, as well as the limitations, applications and specifications.

1.1 Lime sludge

Energy plays a crucial role in the growth of developing countries like India. In the context of low availability of non-renewable energy resources coupled with the requirements of large quantities of energy for building materials like cement, the importance of using industrial waste is very important. While producing paper various wastes are comes out from the various processes in paper industries. The preliminary waste from paper industry is named as Lime sludge.

The Lime sludge contains, low calcium, maximum calcium chloride and minimum amount of silica. Lime sludge behaves like cement because of silica and magnesium properties. This silica improves the setting of the concrete. The raw Lime sludge disposal is shown in fig 1.1. For this, the Lime sludge is used as supplementary cementitious material for partial replacement in the concrete as high performance. By utilizing this waste the strength will be increased and also cost reduction in the concrete is achieved.

1.2 Properties of Lime sludge

The sludge which used in present investigation is brought from ITC (BPL) Bhadrachalam paper industry Private limited Bhadrachalam, Telangana state, India.

Jayeshkumar Pitroda et all [1] (2013), in their research cement has been replaced by waste paper sludge accordingly in the range of 0% (without Lime sludge), 10%, 20%, 30% & 40% by weight for M-25 and M-40 mix.
Concrete mixtures were produced, tested and compared in terms of strength with the conventional concrete. These tests were carried out to evaluate the mechanical properties like compressive strength up to 28 days and split strength for 56 days were taken. As a result, the compressive increased up to 10% addition of Lime sludge and further increased in Lime sludge reduces the strengths gradually. This research work is concerned with experimental investigation on strength of concrete and optimum percentage of the partial replacement by replacing cement via 10%, 20%, 30%, and 40% of Lime sludge. Keeping all this view, the aim of investigation is to find the behavior of concrete like mechanical and durability properties by adding sludge in different proportions in concrete mix. From the literature it was noticed that the work on utilization of Lime sludge in concrete is scarce and hence there is a gap in this area.

1.3 Objective of the Study
1. To utilize Lime sludge as Supplementary Cementitious Materials (SCM)
2. Influence of Lime sludge on the mechanical properties of concrete.
3. Cost effective
4. Eco friendly
5. To find out the better properties of sludge by using less cement content in the mix

2. Materials and Methods
2.1 Materials used
The different materials used in this investigation are-

2.1.1 Cement- ordinary portland cement (OPC) 53 grade cement confirming to IS:12269 was used in this investigation. Few tests like slump test for workability, initial setting time (30 min), Specific gravity (3.15) and fineness of cement were calculated

2.1.2 Fine Aggregate- River sand confirming to IS 383 Zone 2 sand has been used in this experimental program. Specific gravity of fine aggregate is 2.62.

2.1.3 Coarse Aggregate- Machine crushed granite confirming IS 383 and IS 2386, has been used in this experimental program. Specific gravity of coarse aggregate is 2.82.

2.1.4 Water- Water with pH value 6.5 – 8 was used in this investigation.

2.1.5 Lime sludge- While producing paper various wastes are comes out from the various processes in paper industries. The preliminary waste from paper industry is named as Lime sludge. The Lime sludge contains, low calcium, maximum calcium chloride and minimum amount of silica. Lime sludge behaves like cement because of silica and magnesium properties. This silica improves the setting of the concrete.

2.1.6 - Admixture (conplast SP430) -To improve the workability, admixture is used 0.5% of cement weight.

3. Experimental Investigation
In this research work an attempt is made to produce sustainable concrete using Lime sludge. The percentage of Lime sludge is taken as 10%, 20% & 30% replaced with OPC and found out mechanical properties. In this case ordinary Portland cement content is taken as 250kg/m3 to find the better properties of sludge. In order to improve the workability of concrete chemical admixture (CONPLAST SP430) is added. The mix proportion is presented in Table.2

In the laboratory, all the required materials are mixed in rotary mixing machine with addition of Water for 3-5 minutes specimens casted. The concrete is poured into the moulds.

Make sure top surface is well finished and the sizes of the specimens like cube moulds (150mm x 150mm x 150mm), cylindrical moulds (150mm x 300mm) and prism moulds (500mm x 100mm x 100mm). The casted specimens are demoulded after 24 hours and are kept in different curing regimes. The specimens cured in water for 7 days and 28 days.

4. Discussions on Results
4.1 Effect of Lime sludge on compressive strength of concrete-
It is very much evident from the figure 4.1 that there is a steep increase in compressive strength in Lime sludge concrete. Lime sludge was replaced in Ordinary portland cement from 0 to 50% and found out 30% is optimum
A general observation made from the figure is that sorptivity decreases with addition of Lime sludge and it is better than normal concrete.

Fig 4.10 Sorptivity of the cubes immersed up to 10mm in water

5 Cost Analysis
Cost analysis is carried out for 30% replaced Lime sludge in concrete and compared to conventional concrete.

The above table shows cost values up to 30% replacement and the difference in cost from conventional concrete to 30% replaced concrete was Rs. 348/-

5. Conclusions
1. The replacement with 30% gives more compressive strength and reduces beyond addition compared to normal concrete.
2. There is steep increase in flexural strength with 30% replacement
3. The coefficient of sorptivity is better than normal concrete with 30% replacements
4. Less cement content (250 kg/m³) is used to find out better properties of sludge.
5. Hence, it can be concluded that Lime sludge concrete is good enough to satisfy the requirements for compressive strength, flexural strength and sorptivity
6. It was noticed that Lime sludge concrete is economical and eco friendly
