## Keywords

Boolean Function Graph
Domination number
Neighborhood number, Eccentricity.

#### Abstract

For any graph $G$, let $V(G)$ and $E(G)$ denote the vertex set and edge set of $G$ respectively. The Boolean function graph $B\left(K_{p}, I N C, \bar{K}_{q}\right)$ of $G$ is a graph with vertex set $V(G) \cup E(G)$ and two vertices in $B\left(K_{p}\right.$, INC, $\bar{K}_{q}$ ) are adjacent if and only if they correspond to two adjacent vertices of $G$, two nonadjacent vertices of $G$ or to a vertex and an edge incident to it in $G$, For brevity, this graph is denoted by $\bar{B}_{4}(G)$. In this paper, structural properties of the complement $\bar{B}_{4}(G)$ of $B_{4}(G)$ including eccentricity properties are studied. Also, domination number and neighborhood number are found.

## 1. Introduction

Graphs discussed in this paper are undirected and simple graphs. For a graph $G$, let $V(G)$ and $E(G)$ denote its vertex set and edge set respectively. A graph with $p$ vertices and $q$ edges is denoted by $G(p, q)$. If $v$ is a vertex of a connected graph $G$, its eccentricity $e(v)$ is defined by $e(v)=\max \left\{d_{G}(v, u): u \in V(G)\right\}$, where $d_{G}(u, v)$ is the distance between $u$ and $v$ in $G$. The minimum and maximum eccentricities are the radius and diameter of $G$, denoted $r(G)$ and $\operatorname{diam}(G)$ respectively. When $\operatorname{diam}(G)=r(G), G$ is called a self-centered graph with radius r , equivalently G is r -self-centered. A connected graph G is said to be geodetic, if a unique shortest path joins any two of its vertices.

A vertex and an edge are said to cover each other, if they are incident. A set of vertices, which covers all the edges of a graph $G$ is called a point cover for $G$. The smallest number of vertices in any point cover for $G$ is called its point covering number and is denoted by $\alpha_{0}(G)$ or $\alpha_{0}$. A set of vertices in $G$ is independent, if no two of them are adjacent. The largest number of vertices in such a set is called the point independence number of $G$ and is denoted by $\beta_{0}(G)$ or $\beta_{0}$.

Sampathkumar and Neeralagi [12] introduced the concept of neighborhood sets in graphs. A subset $S$ of $V(G)$ is a neighborhood set ( n -set) of G , if $\mathrm{G}=\cup_{\mathrm{v} \in \mathrm{S}}(\langle\mathrm{N}[\mathrm{v}]\rangle$ ), where $\langle\mathrm{N}[\mathrm{v}]\rangle$ is the subgraph of G induced by $\mathrm{N}[\mathrm{v}]$. The neighborhood number $n_{0}(G)$ of $G$ is the minimum cardinality of an $n$-set of $G$.

The concept of domination in graphs was introduced by Ore [2]. A set $S \subseteq V$ is said to be a dominating set in $G$, if every vertex in $\mathrm{V}-\mathrm{S}$ is adjacent to some vertex in S . The domination number $\gamma(\mathrm{G})$ of G is the minimum cardinality of a dominating set. A dominating set with cardinality $\gamma(\mathrm{G})$ is referred as a $\gamma$-set. A dominating set S of a graph G is called an independent dominating set of $G$, if the induced subgraph $\langle S\rangle$ is independent. The minimum cardinality of an independent dominating set of $G$ is called the independent domination number of G and is denoted by $\gamma_{\mathrm{i}}$.

Whitney[14] introduced the concept of the line graph $L(G)$ of a given graph $G$ in 1932. The first characterization of line graphs is due to Krausz. The Middle graph $\mathrm{M}(\mathrm{G})$ of a graph G was introduced by Hamada and Yoshimura[6]. Chikkodimath and Sampathkumar [5] also studied it independently and they called it, the semi-total graph $T_{1}(G)$ of a graph G. Characterizations were presented for middle graphs of any graph, trees and complete graphs in [3]. The concept of total graphs was introduced by Behzad [4] in 1966. Sastry and Raju[13] introduced the concept of quasi-total graphs and they solved the graph equations for line graphs, middle graphs, total graphs and quasi-total graphs. Janakiraman et al., introduced the concepts of Boolean and Boolean function graphs [7-11].

The points and edges of a graph are called its elements. Two elements of a graph are neighbors, if they are either incident or adjacent. The Boolean Function graph $B\left(K_{p}, I N C, \bar{K}_{q}\right)$ of $G$ is a graph with vertex set $V(G) \cup E(G)$ and two vertices in $B\left(K_{p}\right.$, INC, $\overline{\mathrm{K}}_{\mathrm{q}}$ ) are adjacent if and only if they correspond to two adjacent vertices of $G$, two nonadjacent vertices of $G$ or to a vertex and an edge incident to it in G. For brevity, this graph is denoted by $B_{4}(G)$. Two vertices in $\bar{B}_{4}(G)$ are adjacent if and only if they correspond to two adjacent edges of G , two nonadjacent edges of G or to a vertex and an edge not incident to it in G . In this paper, structural properties of the complement $\bar{B}_{4}(G)$ of $B_{4}(G)$ including eccentricity properties are studied. Domination and neighborhood numbers of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ are also found. For graph theoretic terminology, Harary [1] is referred.

## 2. Previous Results

## Observation 2.1. [11]

1. $\mathrm{K}_{\mathrm{p}}$ is an induced subgraph of $\mathrm{B}_{4}(\mathrm{G})$ and subgraph of $\mathrm{B}_{4}(\mathrm{G})$ induced by q vertices is totally disconnected.
2. Number of vertices in $B_{4}(G)$ is $p+q$, since $B_{4}(G)$ contains vertices of both $G$ and the line graph $L(G)$ of $G$.
3. Number of edges in $B_{4}(G)$ is $(p(p-1) / 2)+2 q$
4. For every vertex $v \in V(G), d_{B 4(G)}(v)=p-1+d_{G}(v)$
(a) If G is complete, then $\mathrm{d}_{\mathrm{B} 4(\mathrm{G})}(\mathrm{v})=2(\mathrm{p}-1)$.
(b) If G is totally disconnected, then $\mathrm{d}_{\mathrm{B4}(\mathrm{G})}(\mathrm{v})=\mathrm{p}-1$.
(c) If G has atleast one edge, then $2 \leq \mathrm{d}_{\mathrm{B4}(\mathrm{G})}(\mathrm{v}) \leq 2(\mathrm{p}-1)$ and $\mathrm{d}_{\mathrm{B4} 4 \mathrm{G})}(\mathrm{v})=1$ if and only if $\mathrm{G} \cong 2 \mathrm{~K}_{1}$.
5. For an edge $e \in E(G), d_{B 4(G)}(e)=2$.
6. $\mathrm{B}_{4}(\mathrm{G})$ is always connected.
7. Let $G$ be a $(p, q)$ graph with atleast one edge. If $p$ is odd, then $B_{4}(G)$ is Eulerian if and only if $G$ is Eulerian.
8. If G is r -regular ( $\mathrm{r} \geq 1$ and is odd), then $\mathrm{B}_{4}(\mathrm{G})$ is Eulerian.
9. For any graph $G, B_{4}(G)$ is Hamiltonian if and only if
(i) $G$ is a path or a cycle on atleast three vertices
(ii) Each component of $\mathrm{B}_{4}(\mathrm{G})$ is $\mathrm{K}_{1}, \mathrm{~K}_{2}$ or $\mathrm{P}_{\mathrm{m}}, \mathrm{m} \geq 3$.
$10 . B_{4}(G)$ is self-centered with radius 2 if and only if $G$ is either $C_{3}$ or $C_{3} \cup n K_{1}, n \geq 1$.
10. $B_{4}(G)$ is bi-eccentric with radius 1 and diameter 2 , if and only if $G$ is either $K_{1, n}$ or $K_{1, n} \cup m K_{1}, n \geq 2, m \geq 1$.
$12 . \mathrm{B}_{4}(\mathrm{G})$ is bi-eccentric with radius 2 and diameter 3 , if and only if $\beta_{0}(\mathrm{G}) \geq 2$.

## 3. Main Results

In this section, the properties of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ including traversability and eccentricity properties are studied.

## Observation 3.1.

1. $K_{p}$ is an induced subgraph of $\bar{B}_{4}(G)$ and the subgraph of $\bar{B}_{4}(G)$ induced by $q$ vertices is totally disconnected.
2. Number of edges in $\overline{\mathrm{B}}_{4}(\mathrm{G})$ is $(\mathrm{q}(\mathrm{q}-1) / 2)+\mathrm{q}(\mathrm{p}-2)$
3. For every vertex $v \in V(G)$, degree $v$ in $\bar{B}_{4}(G)$ is $q-d_{G}(v)$.
4. For an edge $e \in E(G)$, degree of $e$ in $\bar{B}_{4}(G)$ is $p+q-3$.
5. For any connected graph $G$ with $p$ vertices, $\bar{B}_{4}(G)$ is disconnected if and only if $G$ is a star on $p$ vertices.
6. If there exists a vertex $v \in V(G)$ such that $v$ is not incident with exactly one edge in $G$, then $v$ is a pendant vertex in $\bar{B}_{4}(G)$.
7. If $v$ is a vertex in $G$ such that $v$ is incident with all the edges of $G$, then $v$ is isolated in $\bar{B}_{4}(G)$.
8. If $G$ is a graph with atleast three vertices, then each vertex of $\bar{B}_{4}(G)$ lies on a triangle and hence girth of $\bar{B}_{4}(G)$ is 2 .
9. If $G$ is a graph with atleast four vertices and atleast one edge, then $\bar{B}_{4}(G)$ is bi-regular if and only if $G$ is regular and is regular if and only if G is totally disconnected.
10.If $G$ is a graph with atleast three vertices, then $\bar{B}_{4}(G)$ has no cut vertices.
11.If $G$ has atleast one edge, then vertex connectivity of $\bar{B}_{4}(G)$ is equal to the edge connectivity of $\bar{B}_{4}(G)=2$.
12.Let $G$ be a $(p, q)$ graph with atleast one edge. If $p$ is odd, then $\bar{B}_{4}(G)$ is Eulerian if and only if $G$ is Eulerian.
10. If $G$ is $r$-regular ( $r \geq 1$ and is odd), then $\bar{B}_{4}(G)$ is Eulerian.
11. For any graph $G, \bar{B}_{4}(G)$ is geodetic if and only if $G$ is either $K_{2}$ or $n K_{1}, n \geq 2$.
12. If $G$ is a graph with atleast four vertices, then $\bar{B}_{4}(G)$ is $P_{4}$ - free.

In the following, a necessary and sufficient condition for $\bar{B}_{4}(G)$ to be Hamiltonian is proved.

## Theorem 3.1.

Let $G$ be any ( $p$. q) graph which is not a star. Then $\bar{B}_{4}(G)$ is hamiltonian if and only if $q \geq p$ and $\operatorname{deg}_{G}(v) \leq 2$, for all $v$ in $G$.

## Proof.

Let G be any $(\mathrm{p}, \mathrm{q})$ graph such that $\mathrm{q} \geq \mathrm{p}$ and $\operatorname{deg}_{\mathrm{G}}(\mathrm{v}) \leq 2$, for all v in G .
Therefore, $\operatorname{deg}_{\overline{\mathrm{B}} 4(\mathrm{G})}(\mathrm{v})=\mathrm{q}-\operatorname{deg}_{\mathrm{G}}(\mathrm{v}) \geq 2$. That is, for every vertex v in G , there exist atleast two edges in G not incident with v. By the construction of $\bar{B}_{4}(G)$, each vertex of $L(G)$ in $\bar{B}_{4}(G)$ is adjacent to ( $\mathrm{p}-2$ ) vertices of $G$ in $\bar{B}_{4}(G)$. A cycle of length $2 p$ in $B_{4}(G)$ can be formed with $p$ vertices of $G$ and $p$ vertices of $L(G)$, each vertex of $G$ followed by a vertex of $L(G)$, that is, $v_{1} e_{1} v_{2} e_{2} \ldots v_{p} e_{p} v_{1}$, where $e_{i} \in E(G)$ is not incident with $v_{i}, v_{i+1}, i=1,2, \ldots,(p-1)$ and $e_{p}$ is not incident with $v_{p}$ and $v_{1}$. Since each pair of vertices in $L(G)$ is adjacent in $\bar{B}_{4}(G)$, the remaining ( $q-p$ ) vertices of $L(G)$ in $\bar{B}_{4}(G)$ can be placed suitably in the above cycle $C_{2 p}$. Therefore, there exists a Hamiltonian cycle in $\bar{B}_{4}(G)$ and hence $\bar{B}_{4}(G)$ is Hamiltonian.

Conversely, let $\overline{\mathrm{B}}_{4}(\mathrm{G})$ be Hamiltonian. Therefore degree of each vertex in $\overline{\mathrm{B}}_{4}(\mathrm{G})$ must be atleast 2 . That is, $\operatorname{deg} \overline{\mathrm{B}} 4(\mathrm{G})(\mathrm{v}) \geq 2$, for all v in G , which implies $\mathrm{q}-\operatorname{deg}_{\mathrm{G}}(\mathrm{v}) \geq 2$.

That is, $\operatorname{deg}_{\mathrm{G}}(\mathrm{v}) \leq \mathrm{q}-2$.
Assume $\mathrm{q}<\mathrm{p}$. Since neither $G$ nor $\overline{\mathrm{G}}$ is a subgraph of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ and each vertex of G in $\overline{\mathrm{B}}_{4}(\mathrm{G})$ is adjacent to (p-2) vertices of $L(G)$ in $\bar{B}_{4}(G)$ in the hamiltonian cycle each vertex of $G$ is followed by a vertex of $L(G)$. This is not possible, if $q<p$. Therefore $\mathrm{q} \geq \mathrm{p}$.

## Remark 3.1.

1. If $G$ is a graph obtained by attaching pendant edges at a vertex of $C_{3}$, then $\bar{B}_{4}(G)$ contains a Hamiltonian path.
2. If $G$ is a graph obtained by subdividing an edge of a star, then $\bar{B}_{4}(G)$ contains a hamiltonian path.

Theorem 3.2.
If $G$ is a tree which is not a star, then $\bar{B}_{4}(G)$ contains a hamiltonian path.

## Proof.

Let G be a tree which is not a star. Then $\mathrm{q}=\mathrm{p}-1$. Since G is not a star, $\overline{\mathrm{B}}_{4}(\mathrm{G})$ contains no isolated vertices. As in Theorem 3.1., there exists a Hamiltonian path in $\bar{B}_{4}(G), v_{1} e_{1} v_{2} e_{2} \ldots v_{p-1} e_{p-1} v_{p}$, where $e_{i} \in E(G)$ is not incident with $v_{i}, v_{i+1}, i=1,2, \ldots,(p-1)$.

## Remark 3.2.

Let $G$ be any graph such that $\bar{B}_{4}(G)$ is connected and $q=p-1$. Then $\bar{B}_{4}(G)$ contains a Hamiltonian path.
In the following, point (line) covering number, (edge) independence number, chromatic number and neighborhood number are found for $\overline{\mathrm{B}}_{4}(\mathrm{G})$.

## Theorem 3.3.

Let G be any ( $\mathrm{p}, \mathrm{q}$ ) graph with atleast three vertices and not totally disconnected.
Then $\alpha_{0}\left(\bar{B}_{4}(\mathrm{G})\right)=\mathrm{q}$.

## Proof.

Since the subgraph of $\bar{B}_{4}(G)$ induced by vertices of $L(G)$ in $\bar{B}_{4}(G)$ is complete, $\alpha_{0}\left(K_{q}\right)=q-1$. Let $\mathrm{e}_{1}, \mathrm{e}_{2}, \ldots, \mathrm{e}_{\mathrm{q}}$ be the q vertices of $L(G)$ in $\bar{B}_{4}(G)$. Then $D=\left\{e_{1}, e_{2}, \ldots, e_{q-1}\right\}$ is a line cover of $K_{q}$ in $\bar{B}_{4}(G)$. The vertex $\mathrm{e}_{q} \in V\left(\bar{B}_{4}(G)\right)$ covers the edges in $\bar{B}_{4}(G)$ of the from ( $\left.v, e_{q}\right)$, where $e_{q} \in E(G)$ is not incident with $v \in V(G)$. Therefore $D \cup\left\{e_{q}\right\} \subseteq V\left(\bar{B}_{4}(G)\right.$ ) is a minimum point cover of $\overline{\mathrm{B}}_{4}(\mathrm{G})$.

## Remark 3.3.

Since $\alpha_{0}\left(\bar{B}_{4}(\mathrm{G})\right)+\beta_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=\mathrm{p}+\mathrm{q}, \beta_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=\mathrm{p}$ and hence $\alpha_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=\beta_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)$ if and only if $\mathrm{p}=\mathrm{q}$.
Theorem 3.4.
Let G be a $(\mathrm{p}, \mathrm{q})$ graph which is not totally disconnected and is not a star. Then line covering number $\alpha_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right.$ ) is given by $\alpha_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)= \begin{cases}\min \{\mathrm{q},\lceil(\mathrm{p}+2 \mathrm{q}) / 2\rceil, & \text { if } \mathrm{q} \geq \mathrm{p} . \\ \mathrm{p}, & \text { if } \mathrm{q}<\mathrm{p} .\end{cases}$

## Proof

## Case 1: $q \geq p$

Subcase 1.a: q is even
Let $v_{1}, v_{2}, \ldots, v_{p}$ be the vertices of $G$ in $\bar{B}_{4}(G)$ and $e_{j k}=\left(v_{j}, v_{k}\right)$ be an edge in $G$ and $e_{j k} \in V\left(\bar{B}_{4}(G)\right)$. Since $q \geq p$, for each edge $e \in E(G)$, there exists a vertex $v_{i} \in V(G)$ not incident with e. Then $\left\{\left(v_{i}, e_{j k}\right) \in E\left(\bar{B}_{4}(G)\right): e_{j k} \in E(G)\right.$ is not incident with vi $\in V(G)$ and $\mathrm{e}_{\mathrm{jk}}$ are distinct\} is a line cover for $\overline{\mathrm{B}}_{4}(\mathrm{G})$. Therefore, $\alpha_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right) \leq \mathrm{q}$. Since the subgraph of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ induced by $q$ vertices of $\mathrm{L}(\mathrm{G})$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$ is complete, $\alpha_{1}\left(\mathrm{~K}_{\mathrm{q}}\right)=\mathrm{q} / 2$ and p vertices of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ are covered by the edges $\left(v_{\mathrm{i}}, \mathrm{e}_{\mathrm{j} k}\right), \mathrm{i}=1,2, \ldots, \mathrm{p}$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$. Therefore, $\alpha_{1}\left(\bar{B}_{4}(\mathrm{G})\right) \leq \mathrm{p}+\mathrm{q} / 2$ and hence $\alpha_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right) \leq \min \{\mathrm{q}, \mathrm{p}+\mathrm{q} / 2\}=\min \{\mathrm{q},(2 \mathrm{p}+\mathrm{q}) / 2\}$.
Subcase 1.b: $q$ is odd
Let $\mathrm{e}_{1}, \mathrm{e}_{2}, \ldots$, $\mathrm{e}_{\mathrm{q}}$ be the q vertices of $\mathrm{L}(\mathrm{G})$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$. Then $\left\langle\left\{\mathrm{e}_{1}, \mathrm{e}_{2}, \ldots, \mathrm{e}_{\mathrm{q}-1}\right\}\right\rangle \mathrm{K}_{\mathrm{q}-1}$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$ and $\alpha_{1}\left(\mathrm{~K}_{\mathrm{q}-1}\right)=(\mathrm{q}-1) / 2$. Let $v_{p} \in V(G)$ be not incident with $e_{q} \in E(G)$. Then the edges $\left(v_{p}, e_{q}\right),\left(v_{i}, e_{j k}\right), i=1,2, \ldots, p-1$ cover the $p$ vertices and the vertex $e_{q}$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$. Therefore, $\left.\alpha_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=\mathrm{p}+(\mathrm{q}-1) / 2=2 \mathrm{p}+\mathrm{q}-1\right) / 2$ and hence $\alpha_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=\min \{\mathrm{q},(2 \mathrm{p}+\mathrm{q}-1) / 2$. Combining Subcase 1.1. and 1.2.,

$$
\alpha_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=\min \{\mathrm{q},\lceil(\mathrm{p}+2 \mathrm{q}) / 2\rceil, \quad \text { if } \mathrm{q} \geq \mathrm{p} .
$$

## Case 2: $\mathrm{q}<\mathrm{p}$

Then the edges $\left(v_{i}, e_{j k}\right) \in E\left(\bar{B}_{4}(G)\right), i=1,2, \ldots, p$, where $e_{j k} \in E(G)$ is not incident with $v_{i} \in E(G)$, cover the vertices of $\bar{B}_{4}(G)$. Therefore, $\alpha_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=\mathrm{p}$.

## Remark 3.4.

Since $\alpha_{1}\left(\bar{B}_{4}(G)\right)+\beta_{1}\left(\bar{B}_{4}(G)\right)=\mathrm{p}+\mathrm{q}$ for a totally disconnected graph G and is not a star, $\beta_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)$ is given by

$$
\beta_{1}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)= \begin{cases}\min \{\mathrm{p},\lceil(\mathrm{q}+1) / 2\rceil, & \text { if } \mathrm{q} \geq \mathrm{p} \\ \mathrm{q}, & \text { if } \mathrm{q}<\mathrm{p}\end{cases}
$$

## Remark 3.5.

When $G \cong K_{1, n},(n \geq 2), \quad \bar{B}_{4}\left(K_{1, n}\right)$ contains an isolated vertex and $\beta_{1}\left(\bar{B}_{4}\left(K_{1, n}\right)\right)=n$.
In the following, chromatic number of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ is found.

## Theorem 3.5.

Let G be $\mathrm{a}(\mathrm{p}, \mathrm{q})$ graph. Then
$\chi\left(\bar{B}_{4}(\mathrm{G})\right)= \begin{cases}\mathrm{q}, & \text { if } \delta(\mathrm{G}) \geq 1 \\ \mathrm{q}+1, & \text { if } \delta(\mathrm{G})=0\end{cases}$

## Proof.

Case 1: $\delta(\mathrm{G}) \geq 1$
The subgraph of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ induced by all the vertices of $\mathrm{L}(\mathrm{G})$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$ is a complete graph on q vertices and $\chi\left(\mathrm{K}_{\mathrm{q}}\right)=\mathrm{q}$. That is, vertices of $L(G)$ in $\bar{B}_{4}(G)$ are coloured with $q$ colours. Let $v_{i} \in V(G)$ and $e_{i} \in E(G)$ be an edge incident with $v_{i}$. Since $\delta(G) \geq 1$, such an edge exists in $G$. Then $v_{i}, e_{i} \in V\left(\bar{B}_{4}(G)\right)$. Now colour the vertex $v_{i}$ in $\bar{B}_{4}(G)$ by the colour given to $e_{i}$ in $\bar{B}_{4}(G)$, since $v_{i}$ and $e_{i}$ are independent vertices in $\overline{\mathrm{B}}_{4}(\mathrm{G})$. Since no two vertices of G are adjacent in $\overline{\mathrm{B}}_{4}(\mathrm{G}), \chi\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=\mathrm{q}$.
Case 2: $\delta(\mathrm{G})=0$.
Let v be an isolated vertex in G . Then $\mathrm{v} \in \mathrm{V}\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)$ is adjacent to all the vertices of $\mathrm{L}(\mathrm{G})$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$. Therefore v can be coloured with a new colour. Hence $\mathrm{V}\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right.$ ) is $\mathrm{q}+1$ colourable and $\mathrm{V}\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right.$ ) cannot be coloured with fewer than $\mathrm{q}+1$ colours. Therefore, $\chi\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=\mathrm{q}+1$.

In the following, domination number of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ is found.

## Remark 3.6.

Since there is no vertex of degree $\mathrm{p}+\mathrm{q}-1$ in $\overline{\mathrm{B}}_{4}(\mathrm{G}), \gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right) \geq 2$.

## Theorem 3.6.

For any graph $G$ with atleast one edge, $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=2$ if and only if $\beta_{1}(\mathrm{G}) \geq 2$.
Proof.
Let $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=2$. Then there exists a minimum dominating set D of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ containing two vertices.
Case 1: $\mathrm{D}=\left\{\mathrm{v}_{1}, \mathrm{v}_{2}\right\} \subseteq \mathrm{V}(\mathrm{G})$
Since no two vertices of $G$ are adjacent in $\bar{B}_{4}(G)$ and $G$ contains atleast one edge, $D$ cannot be dominating set of $\bar{B}_{4}(G)$.
Case 2: $D=\{v, e\} \subseteq V\left(\bar{B}_{4}(G)\right)$, where $v \in V(G)$
and $e \in E(G)$.
Let $e=(u, w)$, where $u, w \in V(G)$. Then $u, w \in V\left(\bar{B}_{4}(G)\right)$ and are not adjacent to any of the vertices in $D$.
Case 3: $\mathbf{D}=\left\{\mathrm{e}_{1}, \mathrm{e}_{2}\right\} \subseteq \mathrm{E}(\mathrm{G})$
Then $\left\{e_{1}, e_{2}\right\} \subseteq V\left(\bar{B}_{4}(G)\right)$. Since $D$ is a dominating set of $\bar{B}_{4}(G), e_{1}$ and $e_{2}$ are independent edges in $G$. Therefore $\beta_{1}(G) \geq 2$.
Conversely, assume $\beta_{1}(G) \geq 2$. Then there exist atleast two independent edges say $e_{1}, e_{2}$ in $G$. Let $D^{\prime}$ be the set of vertices
in $\overline{\mathrm{B}}_{4}(\mathrm{G})$ corresponding to the edges $\mathrm{e}_{1}$ and $\mathrm{e}_{2}$ in G . Then $\mathrm{D}^{\prime}$ is a dominating set of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ and $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right) \leq 2$. But $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right) \geq 2$.
Therefore $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=2$.

## Theorem 3.7.

If $G$ is a graph with atleast one edge, then $\gamma\left(\bar{B}_{4}(G)\right)=\gamma_{i}\left(\bar{B}_{4}(G)\right) \leq 3$.

## Proof.

Let $\mathrm{e}=(\mathrm{u}, \mathrm{v}) \in \mathrm{E}(\mathrm{G})$, where $\mathrm{u}, \mathrm{v} \in \mathrm{V}(\mathrm{G})$.
Then $D=\{u, v, e\} \subseteq V\left(\bar{B}_{4}(G)\right)$ is a dominating set of $\bar{B}_{4}(G)$ and is independent. Hence, $\gamma\left(\bar{B}_{4}(G)\right)=\gamma_{i}\left(\bar{B}_{4}(G)\right) \leq 3$.

## Remark 3.7.

a. If $G$ is a star or a cycle on three vertices, then $\gamma\left(\bar{B}_{4}(G)\right)=\gamma_{i}\left(\bar{B}_{4}(G)\right)=3$.
b. For any graph $G$, let $D$ be subset of $E(G)$ with atleast two vertices and $\left\langle D>\right.$ is not a star. Then the set $D^{\prime}$ vertices of $\bar{B}_{4}(G)$ corresponding to the edges of $G$ is a dominating set of $\bar{B}_{4}(G)$ and $D$ contains exactly two vertices, then $D^{\prime}$ is a dominating set of $\bar{B}_{4}(G)$ if and only if edges of $\langle D>$ are independent.

## Theorem 3.8.

Let G be a graph which is not a star. Then $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=\gamma(\mathrm{G})=2$ if and only if either there exists a dominating edge in G or G is a union of stars.

## Proof.

Let there exist a dominating edge e in G . Then each vertex in G is adjacent to atleast one of the end vertices of e . Therefore, $\gamma(\mathrm{G})=2$. Since $G$ is a not a star, there exist atleast two independent edges in $\underline{G}$. Let $e_{1}, e_{2}$ be the vertices in $\bar{B}_{4}(G)$ corresponding to the two independent edges in $G$. Then $D=\left\{e_{1}, e_{2}\right\}$ is a dominating set of $\bar{B}_{4}(G)$. Therefore, $\gamma\left(\bar{B}_{4}(G)\right)=2$. Similarly, if $G$ is a union of stars, then also $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=2$.

Conversely, assume $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=\gamma(\mathrm{G})=2$. Then there exists a dominating set D of G with two vertices. That is, either G contains a dominating edge or $\mathrm{G} \cong \mathrm{K}_{1, \mathrm{n}} \cup \mathrm{K}_{1, \mathrm{~m}}, \mathrm{n}, \mathrm{m} \geq 1$.

## Theorem 3.9.

For any graph $\mathrm{G}, \gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=\gamma(\mathrm{L}(\mathrm{G}))=2$ if and only if there exist two independent edges in G such that each edge in G is adjacent to atleast one of those independent edges, where $L(G)$ is the line graph of $G$.

## Proof.

Let there exist two independent edges in $G$ such that each edge in $G$ is adjacent to one of the independent edges. Let $e_{1}$ and $e_{2}$ be the corresponding vertices in $L(G)$. Then $D=\left\{e_{1}, e_{2}\right\} \subseteq V(L(G))$ is a dominating set of both $L(G)$ and $\bar{B}_{4}(G)$. Therefore $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=\gamma(\mathrm{G})=2$.

Conversely, assume $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=\gamma(\mathrm{G})=2$. Then there exists minimum dominating set D of both $\mathrm{L}(\mathrm{G})$ and $\overline{\mathrm{B}}_{4}(\mathrm{G})$ containing two vertices. Let $D=\left\{e_{1}, e_{2}\right\} \subseteq V(L(G))$, where $e_{1}$ and $e_{2}$ are edges in $G$. Since $D$ is a dominating set of $L(G)$, each edge in $G$ is adjacent to atleast one of $e_{1}$ and $e_{2}$. Similarly, since $D$ is also a dominating set of $\bar{B}_{4}(G), e_{1}$ and $e_{2}$ must be independent edges in $G$. Therefore, there exist two independent edges $e_{1}$ and $e_{2}$ in $G$ such that each edge in $G$ is adjacent to atleast one of $e_{1}$ and $e_{2}$.

## Remark 3.8.

For any graph G, if $\gamma(\mathrm{L}(\mathrm{G})) \geq 3$, then $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right) \neq \gamma(\mathrm{G})$.

## Theorem 3.10.

For any graph G, $4 \leq \gamma\left(\mathrm{B}_{4}(\mathrm{G})\right)+\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right) \leq \alpha_{0}(\mathrm{G})+2$.

## Proof.

Let $\beta_{1}(\mathrm{G}) \geq 2$. Then $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=2$ and $\gamma\left(\mathrm{B}_{4}(\mathrm{G})\right) \leq \alpha_{0}(\mathrm{G})$.
Therefore $\gamma\left(\mathrm{B}_{4}(\mathrm{G})\right)+\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right) \leq \alpha_{0}(\mathrm{G})+2$
Let $\beta_{1}(\mathrm{G})=1$. If $\mathrm{G} \cong \mathrm{K}_{1, \mathrm{n}}, \mathrm{n} \geq 2$, then $\leq \gamma\left(\mathrm{B}_{4}(\mathrm{G})\right)+\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=1+3=4$. If $\mathrm{G} \cong \mathrm{C}_{3}$, then $\gamma\left(\mathrm{B}_{4}(\mathrm{G})\right)=\alpha_{0}(\mathrm{G})=2$ and $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=3$. Therefore $\gamma\left(\mathrm{B}_{4}(\overline{\mathrm{G}})\right)+\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right) \geq 4$.

Hence $4 \leq \gamma\left(\mathrm{B}_{4}(\mathrm{G})\right)+\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right) \leq \alpha_{0}(\mathrm{G})+2$.
The lower bound is attained, when $G \cong K_{1, n}, n \geq 2$ and the upper bound is attained for all graphs $G$ with $\beta_{1}(G) \geq 2$ and $G \cong C_{3}$.

## Theorem 3.11.

For any graph $G$ with $q$ edges, $\gamma\left(\bar{B}_{4}(G)\right)=\alpha_{0}\left(\bar{B}_{4}(G)\right)$ if and only if $G$ is one of the following graphs. $2 \mathrm{~K}_{2} \cup \mathrm{mK}_{1}, \mathrm{C}_{3} \cup \mathrm{mK}_{1}$, $K_{1, n} \cup \mathrm{mK}_{1}, \mathrm{~m} \geq 0, \mathrm{n} \geq 3$.

## Proof.

$\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=2$ or 3 . But $\alpha_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=\mathrm{q}$. Therefore, $\mathrm{q}=2$ or 3 . If $\beta_{1}(\mathrm{G}) \geq 2$, then $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=2$ and $\alpha_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=2$. Therefore $\mathrm{G} \cong 2 \mathrm{~K}_{2} \cup \mathrm{mK}_{1}, \mathrm{~m} \geq 0$.

If $\beta_{1}(G)=1$, then $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=\alpha_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=3$. Therefore $\mathrm{G} \cong \mathrm{C}_{3} \cup \mathrm{mK}_{1}$ or $\mathrm{K}_{1, \mathrm{n}} \cup \mathrm{mK}_{1}, \mathrm{~m} \geq 0, \mathrm{n} \geq 3$.

## Theorem 3.12.

Let G be a graph with atleast three vertices and not totally disconnected.
Then $\gamma\left(\bar{B}_{4}(G)\right)=\beta_{0}\left(\bar{B}_{4}(G)\right)$ if and only if $G$ is one of the following graphs. $C_{3}, P_{3}$ and $K_{2} \cup K_{1}$.
Proof.
$\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)=2$ or 3 . But $\beta_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=\mathrm{p}$. Therefore $\mathrm{p}=2$ or 3 . Therefore $\mathrm{G} \cong \mathrm{C}_{3}, \mathrm{P}_{3}$ or $\mathrm{K}_{2} \cup \mathrm{~K}_{1}$. In the following neighborhood number $n_{0}\left(\bar{B}_{4}(G)\right)$ of $\bar{B}_{4}(G)$ is found.

## Theorem 3.13.

Let $G$ be any graph containing atleast one edge. Then $n_{0}\left(\bar{B}_{4}(G)\right)=2$ or 3 .
Proof.
Case1: $\beta_{1}(\mathrm{G}) \geq 2$.
Then there exist atleast two independent edges in G. Let $e_{1}$, $e_{2}$ be the vertices in $\bar{B}_{4}(G)$ corresponding to independent edges in G. Then $\mathrm{D}=\left\{\mathrm{e}_{1}, \mathrm{e}_{2}\right\} \subseteq \mathrm{V}\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right)$ is a dominating set of $\overline{\mathrm{B}}_{4}(\mathrm{G})$.

Let $e_{1}=\left(u_{1}, v_{1}\right)$, where $u_{1}, v_{1} \in V\left(\bar{B}_{4}(G)\right)$.
$N_{\bar{B} 4(G)}\left(e_{1}\right)=\left\{V\left(L(G)-\left\{e_{1}\right\}, V(G)-\left\{u_{1}, v_{1}\right\}\right\}\right.$. Therefore, each edge in $\left\langle V\left(\bar{B}_{4}(G)\right)-D\right\rangle$ belongs to $\left\langle N\left(e_{1}\right)\right\rangle$ and hence $D$ is an $n$-set for $\overline{\mathrm{B}}_{4}(\mathrm{G})$ and $\mathrm{n}_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right) \leq 2$.

Since $\gamma\left(\overline{\mathrm{B}}_{4}(\mathrm{G})\right) \geq 2, \quad \mathrm{n}_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right) \geq 2$. Therefore, $\mathrm{n}_{0}\left(\overline{\mathrm{~B}}_{4}(\mathrm{G})\right)=2$.
Case 2: $\beta_{1}(G)=1$
Then $\mathrm{G} \cong \mathrm{C}_{3}$ or $\mathrm{K}_{1, \mathrm{n}}, \mathrm{n} \geq 1$
If $G \cong C_{3}$ or $K_{1, n}, n \geq 1$, then $n_{0}\left(\bar{B}_{4}(G)\right)=3$.
In the following, distance between any two vertices of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ are found.

## Lemma 3.1.

Let $G$ be a graph which is not a star. If $v_{1}$ and $v_{2}$ are any two vertices in $G$, then distance $d\left(v_{1}, v_{2}\right)$ between $v_{1}$ and $v_{2}$ in $\bar{B}_{4}(G)$ is 2 or 3 .

## Proof.

Let $v_{1}, v_{2} \in G$. Then $v_{1}, v_{2} \in \bar{B}_{4}(G)$. Since no two vertices in $G$ are adjacent in $\bar{B}_{4}(G), d\left(v_{1}, v_{2}\right) \geq 2$ in $\bar{B}_{4}(G)$.
Let e be an edge in $G$ not incident with both $v_{1}$ and $v_{2}$. Then $v_{1} e v_{2}$ is a geodesic path in $\bar{B}_{4}(G)$ and hence $d\left(v_{1}, v_{2}\right)=2$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$.

Assume each edge in $G$ is incident with atleast one of $v_{1}$ and $v_{2}$. That is, $\left\{v_{1}, v_{2}\right\}$ is a point cover of G. Let $e_{1}$ be an edge in $G$ incident with $v_{1}$ but not $v_{2}$ and $e_{2}$ be an edge in $G$ incident with $v_{2}$ but not $v_{1}$. (This is possible, since $G$ is not a star). Then $v_{1} e_{2} e_{1} v_{2}$ is a geodesic path in G .

Therefore, $\mathrm{d}\left(\mathrm{v}_{1}, \mathrm{v}_{2}\right)=3$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$.

## Lemma 3.2.

Let $G$ be a graph which is not a star. If $v \in V(G)$ and $e \in E(G)$, then the distance between $v$, e in $\bar{B}_{4}(G)$ is atmost 2 and if $e_{1}$, $e_{2} \in E(G)$, then distance between $e_{1}$ and $e_{2}$ in $\bar{B}_{4}(G)$ is 1 .

## Proof.

(i) Let $\mathrm{v} \in \mathrm{V}(\mathrm{G})$ and $\mathrm{e} \in \mathrm{E}(\mathrm{G})$. If e is not incident with v in G , then $\mathrm{d}(\mathrm{v}, \mathrm{e})=1$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$. Let e be incident with v in G . Since G is not a star, there exists an edge $e_{1}$ in $G$ not incident with $v$ in $G$.

Then $v, e, e_{1} \in V\left(\bar{B}_{4}(G)\right)$ and ve $e_{1}$ e is a geodesic path in $\bar{B}_{4}(G)$. Hence $d(v, e)=2$ in $\bar{B}_{4}(G)$.
(ii) Let $e_{1}, e_{2} \in E(G)$. Then $e_{1}, e_{2} \in V(L(G))$. Since any vertices of $L(G)$ in $\bar{B}_{4}(G)$ are adjacent, $\mathrm{d}\left(\mathrm{e}_{1}, \mathrm{e}_{2}\right)=1$ in $\overline{\mathrm{B}}_{4}(\mathrm{G})$.

## Observation 3.2.

From Lemma 3.1. and Lemma 3.2., it is observed that, if $G$ is not a star, then
a. Eccentricity of a vertex $v$ in $V\left(\bar{B}_{4}(G)\right) \cap V(G)$ is 2 or 3 and eccentricity of a vertex e in $V\left(\bar{B}_{4}(G)\right) \cap V(L(G))$ is 2 .
b. Radius of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ is 2 and diameter of $\overline{\mathrm{B}}_{4}(\mathrm{G})$ is 2 or 3 .
c. $\overline{\mathrm{B}}_{4}(\mathrm{G})$ is self-centered with radius 2 if and only if for every pair of vertices $u$, $v$ in $G$, there exists atleast one edge in $G$ not incident with both $u v$ in $G$. That is, there exists no point cover of $G$ containing two vertices.
d. $\bar{B}_{4}(G)$ is bieccentric with radius 2 and diameter 3 if and only if there exists a point cover of $G$ containing two vertices.

## Example 3.1.

a. $\overline{\mathrm{B}}_{4}\left(\mathrm{P}_{\mathrm{n}}\right)(\mathrm{n} \geq 6), \overline{\mathrm{B}}_{4}\left(\mathrm{C}_{\mathrm{n}}\right)(\mathrm{n} \geq 5), \overline{\mathrm{B}}_{4}\left(\mathrm{~K}_{\mathrm{n}}\right)(\mathrm{n} \geq 4)$ are self-centered with radius 2 .
b. $\overline{\mathrm{B}}_{4}\left(\mathrm{C}_{\mathrm{n}}\right)(\mathrm{n}=3,4)$ are bieccentric with radius 2 and diameter 3 .
