#### Abstract

The solid phase FTIR and FT-Raman spectra of 1-Benzylimidazole (BI) have been recorded in the regions $4000-400 \mathrm{~cm}^{-1}$ and $3500-100 \mathrm{~cm}^{-1}$, respectively. The optimized geometry, frequency and intensity of the vibrational bands, NBO analysis, HOMO- LUMO study of BI in DFT levels of theory using B3LYP/6-31G and B3LYP/6-311+G basis set. The harmonic vibrational frequencies were calculated and the scaled values have been compared with experimental FTIR and FT-Raman spectra. A detailed interpretation of the vibrational spectra of the title compound has been made on the basis of the calculated potential energy distribution (PED). Stability of the molecule arising from hyperconjucative interactions leading to its bioactivity, charge delocalization have been analyzed using natural bond orbital (NBO) analysis. The calculated HOMO-LUMO energies shows that charge transfer occur within the molecule. The observed and calculated frequencies are found to be in good agreement.

## Introduction

Imidazole and its derivatives have received a great deal of interest from spectro scopists owing to their strong cardiotonic [1], analgestic [2], anti-inflammatory [3,4] and antimicrobial activities [5-8]. Imidazole nucleus forms the building block of some well known components of human organisms, i.e. the amino acid histidine, vitamine B12, a component of DNA base structure and purines, histamine and biotin. It is also present in the structure of many natural synthetic drug molecules, e.g. cimetidine, azomycin and metronidazole [9]. They are also used in many drugs as an inducer of phase 1 and 11 enzymes with wide spectrum detection of precarcinogen in short-term bioassays, hepatic levels of cytochrome P-450 (CYP) and mutagenic activation of various carcinogens [10]. Their inhibitory properties against the replication of poliviruses, adenosine deaminase, and casein kinase have been well demonstrated [11]. Some attempts were made for the interpretations of the vibrational spectra of imidazole derivatives [12]. Literature survey reveals that to the best of our knowledge, the results based on Quantum chemical calculations, FT-IR and FT-Raman spectral analyses on 1-Benzylimidazole (BI) have no reports. Here we reported detailed interpretations of the infrared and Raman spectra based on the theoretical results, which are acceptable and supportable to each other. In the present work, we have attempted to interpret the vibrational spectra of BI by using B3LYP level of theory throughout with the, $6-31 \mathrm{G}$ and 6 $311+\mathrm{G}$, basis sets are implemented in the Gaussian 09 program suite[13].

## Experimental method

BI was provided by Lancaster Chemical Company, UK. which is of spectroscopic grade and hence used for recording the spectra as such without any further purifications. The room temperature Fourier Transform infrared spectrum of BI was
measured in the $4000-400 \mathrm{~cm}^{-1}$ region at a resolution of $\pm 1 \mathrm{~cm}^{-1}$ using BRUKER IFS-66V FT-IR Spectrometer equipped with a KBr pellets were used in the spectral measurements. The FTRaman spectrum was recorded on a BRUKER IFS-66V model interferometer equipped with an FRA - 106 FT-Raman accessory in the $3500-100 \mathrm{~cm}^{-1}$ stokes region using the 1064 nm line of a Nd :YAG laser for excitation operating at 200 mW power.

## Computational details

Analysis of molecular geometry optimizations, energy, and vibrational frequencies was carried out with the Gaussian 09 software package [14] at the DFT (B3LYP) levels supplemented with the standard $6-31 \mathrm{G}$ and $6-311+\mathrm{G}$ basis sets. Cartesian representation of the theoretical force constants has been computed at optimized geometry. Vibrational modes were assigned by means of visual inspection using the GAUSSVIEW [15] program. Data revealed that DFT calculations using a basis set incorporating polarized functions yielded results that are in better agreement with the experimental data. For the plots of simulated IR and Raman spectra, pure Lorentzian band shapes were used with a band width of $\pm 1 \mathrm{~cm}^{-1}$. Prediction of Raman intensities was carried out by the following procedure. The Raman activities ( Si ) calculated by the Gaussian 09 program were converted to relative Raman intensities (Ii) using the following relationship derived from the basic theory of scattering.

$$
\begin{equation*}
I_{i}=\frac{f\left(v_{\mathrm{o}}-v_{i}\right)^{4} s_{i}}{v_{i}\left[1-\exp \left(\frac{-h c v_{i}}{k t}\right)\right]} \tag{1}
\end{equation*}
$$

where $v_{0}$ is the exciting wavenumber $\left(\mathrm{cm}^{-1}\right.$ units $v_{i}$ is the vibrational wavenumber of the $\mathrm{i}^{\text {th }}$ normal mode, $\mathrm{h}, \mathrm{c}$ and k are universal constant and $f$ is a suitably chosen common normalization factor for all peak intensities.

Natural bond orbital analysis (NBO) was also performed by the Gaussian 09 W program at the B3LYP level of theory analysis transforms the canonical delocalized Hartree-Fork (HF) Molecular orbital's (MO) into localized MOs that are closely tied to chemical bonding concepts. This process involves sequential transformation of non-orthogonal atomic orbital's (AOs) to the sets of Natural atomic orbital's (NAOs), Natural hybrid orbital's (NHOs) Natural bond orbital's (NBOs). The localized basis sets are completely described the wave functions in the most economic method, as electron density and other properties that are described by the minimum amount of filled NBO. The interaction between filled and anti-bonding (or) Rydberg orbital's represented the deviation of the molecule from the Lewis structure and be used as the measure of delocalization. This non-covalent bonding anti-bonding charge transfer interactions can be quantitatively described in terms of the second order perturbation interaction energy $\left(\mathrm{E}^{(2)}\right)$ [16-19].

## Results and discussion

## Molecular geometry

The molecular structure of a BI along with numbering of atoms is shown in Fig. 1. The maximum number of potentially active observable fundamentals of a non-liner molecule that contains N atoms is equal to (3n-6), apart from three translational and three rotational degrees of freedom [20]. NALPA having 22 atoms with 60 Normal modes of vibrations which are distributed amongst the symmetry species as (3N-6) $v_{\text {vib }}=41 A^{\prime}$ (in-plane) +19 " (out-of-plane). The A' vibrations are totally symmetric and give rise to polarized Raman lines whereas A" vibrations are antisymmetric and give rise to depolarized Raman lines. The _observed and simulated spectra of the title compound are shown in Fig 2 and 3 respectively.

Fig 1. Optimized geometrical structure and atomic labeling of 1-Benzylimidazole

Fig 2. Observed FT-IR and simulated spectrum of 1Benzylimidazole

Normal coordinate analysis was carried out to provide a complete assignment of the fundamental vibrational frequencies for the molecule. For this purpose the full set of standard internal coordinates are listed in Table 1. From these a redundant set of local symmetry coordinates was constructed by suitable linear combinations of internal coordinates following the recommendations of Fogarasi and Puly et al.[21-23] and are given in Table 2. The theoretically calculated force fields were transformed to this later set of vibrational co-ordinates and are used in all subsequent calculations. The most optimized geometrical parameters (bond length, bond angle and dihedral angle) were also calculated by B3LYP/6-31G and B3LYP/6$311+\mathrm{G}$ basis sets, which are depicted in Table 3.

## Vibrational assignments

The detailed vibrational analysis of fundamental modes of BI along with the FT-IR and FT-Raman experimental frequencies and the unscaled and scaled vibrational frequencies using B3LYP/6-31G and B3LYP/6-311+G basis sets are presented in Table 4.

## $\mathbf{C}-\mathbf{H}$ vibrations

Aromatic compounds commonly exhibit multiple weak bands in the region $3100-3000 \mathrm{~cm}^{-1}$ due to aromatic $\mathrm{C}-\mathrm{H}$ stretching vibrations [24-27]. The bands appeared at 3090, 3068, 3045, 3022, $3000,2954,2908 \mathrm{~cm}^{-1}$ in FT-IR spectrum and 3091, 3070, $2952 \mathrm{~cm}^{-1}$ in FT-Raman spectrum are assigned to $\mathrm{C}-\mathrm{H}$ ring stretching vibrations. The band identified at 3225 , 3176, 3153, 3128, 3109, 3065, 3057, $2975 \mathrm{~cm}^{-1}$ in B3LYP/631 G and $3085,3072,3044,3025,2994,2950,2910 \mathrm{~cm}^{-1}$ in B3LYP/6-311+G methods are assigned to $\mathrm{C}-\mathrm{H}$ ring stretching vibrations. The $\mathrm{C}-\mathrm{H}$ in-plane and out-of-plane bending vibrations generally lie in the range $1000-1300 \mathrm{~cm}^{-1}$ and $950-$ $800 \mathrm{~cm}^{-1}$ [28,29], respectively. In the present case, eight C-H inplane bending vibrations of the title compound identified at $1508,1489,1387,1348,1312,1287,1256,1038 \mathrm{~cm}^{-1}$ in B3LYP/6-31G and $1445,1412,1340,1270,1282,1225,1206$, $1002 \mathrm{~cm}^{-1}$ in B3LYP/ 6-311+G methods are assigned to $\mathrm{C}-\mathrm{H}$ inplane bending vibrations. The $\mathrm{C}-\mathrm{H}$ out-of-plane bending vibrations are observed at $979,831,738,626,614 \mathrm{~cm}^{-1}$ in FT-IR spectrum and $910,853,819,614 \mathrm{~cm}^{-1}$ in FT-Raman spectrum. According to the literature, the in-plane and out-of-plane bending vibrations are found to be lower than their characteristic regions due to the substitution of the $\mathrm{CH}_{2}$.

## $\mathbf{C H}_{2}$ Vibrations

For the assignments of $\mathrm{CH}_{2}$ group frequencies, basically six fundamentals can be associated to each $\mathrm{CH}_{2}$ group namely, $\mathrm{CH}_{2} \mathrm{ss}$ (symmetric stretch); $\mathrm{CH}_{2}$ ass (asymmetric stretch); $\mathrm{CH}_{2}$ sciss (scissoring) and $\mathrm{CH}_{2}$ rock (rocking) which belongs to
in-plane vibrations. In addition to that, $\mathrm{CH}_{2}$ wag (wagging) and $\mathrm{CH}_{2}$ twist group would be expected to be depolarized for out-ofplane symmetry species. Here, the title molecule BI under consideration possesses one $\mathrm{CH}_{2}$ group give rise to 6 fundamental modes of vibration. The anti symmetric $\mathrm{CH}_{2}$ stretching vibrations are generally observed in the regions 3100$3000 \mathrm{~cm}^{-1}$ respectively; while the symmetric stretch will appear between 3000 and $2900 \mathrm{~cm}^{-1}$. The calculated $\mathrm{CH}_{2}$ asymmetric vibrations were identified at $2933 \mathrm{~cm}^{-1}$ in B3LYP/6-31G and $2812 \mathrm{~cm}^{-1}$ in B3LYP/6-311+G methods and symmetric vibrations are found at 2859 in B3LYP/6-31G and $2750 \mathrm{~cm}^{-1}$ in B3LYP/6-311+Gmethod. According to the literature, the stretching vibrations are found to be lower than their characteristic regions due to the substitution of the CH 2 , benzene group. The bands corresponding to scissoring, wagging, rocking and twisting vibrations of $\mathrm{CH}_{2}$ groups are summarized in Table 4. These assignments are also supported by literature data as well as computed harmonics [30].

## CC Vibrations

The position and intensity of ring stretching vibrations depend on the nature of the ring and the type of substitution. In BI, FT-IR bands at $1976,1895,1825,1686,1512,1375 \mathrm{~cm}^{-1}$ and FT-Raman bands at $1506,1456,1368,1182 \mathrm{~cm}^{-1}$ have been assigned to aromatic CC stretching vibrations. The ring in-plane and out of plane bending vibrations are assigned in the characteristic regions. The ring stretching vibrations are all coupled vibrations, some vibrations coupled with $\mathrm{C}-\mathrm{H}$ bending and some with $\mathrm{C}-\mathrm{CH}_{2}$ bending and some with $\mathrm{C}-\mathrm{C}-\mathrm{N}$ stretching vibrations. Small changes due to the changes in force constant/reduced mass ratio resulting mainly due to the extent of mixing between ring and substituent group [31]. The absorption involves stretching of bands in the ring and interaction between these stretching.

## $\mathbf{C}-\mathbf{N}$ vibrations

The identification of $\mathrm{C}-\mathrm{N}, \mathrm{C}=\mathrm{N}$ vibrations is a difficult task, since the mixing of vibrations is possible in this region. Silverstein et al. [32] assigned the $\mathrm{C}-\mathrm{N}$ stretching vibrations in the range $1382-1266 \mathrm{~cm}^{-1}$ for aromatic amines. In the present work, the bands observed at 1651, and $1605 \mathrm{~cm}^{-1}$ in FT-IR spectrum and $1582 \mathrm{~cm}^{-1}$ in FT-Raman spectrum are assigned to $\mathrm{C}-\mathrm{N}$ stretching vibrations. The theoretically computed value of $\mathrm{C}-\mathrm{N}, \mathrm{C}=\mathrm{N}$ stretching vibrations also falls in the region $1689,1644,1635 \mathrm{~cm}^{-1}$ and $1650,1600,1586 \mathrm{~cm}^{-1}$ by both B3LYP/6-31G and B3LYP/6-311+G methods, and the vibrations are found to be higher than their characteristic regions. This is indicating that the impact of substitution $\mathrm{CH}_{2}$ group in the molecule influence the vibration of aromatic $\mathrm{C}-\mathrm{H}$.

## NBO analysis

Natural bond orbital analysis gives the accurate possible natural Lewis structure picture of $\Phi$ because all orbital are mathematically chosen to include the highest possible percentage of the electron density. Interaction between both filled and virtual orbital spaces was correctly explained by the NBO analysis and it could enhance the analysis of intra- and intermolecular interactions. The second-order Fock matrix was carried out to evaluate donor (i)-acceptor (j) i.e. interaction between donor-level bonds and acceptor-level bonds in the NBO analysis [33], The result of interaction is a loss of occupancy from the concentration of electron NBO of the idealized Lewis structure into an empty non-Lewis orbital. For each donor (i) and acceptor ( j ), the stabilization energy $\mathrm{E}^{(2)}$ associates with the delocalization $\mathrm{i} \rightarrow \mathrm{j}$ is follows:

$$
\begin{equation*}
E^{(2)}=\Delta E y=q_{i} \frac{F(i, j)^{2}}{\varepsilon_{j}-\varepsilon_{i}} \tag{2}
\end{equation*}
$$

Where $\mathrm{q}_{\mathrm{i}}$ is the donor orbital occupancy, are $\varepsilon_{\mathrm{j}}$ and $\varepsilon_{\mathrm{i}}$ are diagonal elements and $F(i, j)$ is the off-diagonal NBO Fock matrix element. A natural bond orbital analysis provide an efficient method for studying intra- and intermolecular bonding and interaction between bonds, and also provides a convenient basis for investigating charge transfer or conjugative interaction in molecular systems. Some electron donor orbital, acceptor orbital, and the interacting stabilization energy resulted from second-order perturbation theory are reported [34]. The larger the $\mathrm{E}^{(2)}$ value the more intensive the interaction between electron donors and electron acceptor, i.e., the more donation tendency from electron donors to electron acceptors and the greater the extent of conjugation of the whole system [35]. Delocalization of electron density between occupied Lewis type (bond or lone pair) NBO orbitals and formally unoccupied (antibond or Rydberg) non-Lewis NBO orbital corresponds to a stabilizing donor-acceptor interaction. NBO analysis has been performed on BI at the B3LYP/6-311G level in order to elucidate the intramolecular rehybridization and delocalization of electron density within the molecule.

The most important interactions in BI having lone pair LP (1) $\mathrm{N}_{3}$ with that of anti bonding $\mathrm{N}_{1}-\mathrm{C}_{2}$, results in the stabilization of $6.86 \mathrm{~kJ} / \mathrm{mol}$, which denotes larger delocalization. The maximum energy transfer occurs from LP (1) $\mathrm{N}_{1}$ to $\mathrm{C}_{2}-\mathrm{N}_{3}(44.67$ $\mathrm{kJ} / \mathrm{mol}$ ), respectively, as shown in Table 5.

## HOMO-LUMO

The conjugated molecules are characterized by a highest occupied molecular orbital-lowest unoccupied molecular orbital (HOMO-LUMO) separation, which is the result of a significant degree of intermolecular charge transfer (ICT) from the endcapping electron-donor to the efficient electron acceptor group through p conjugated path. The strong charge transfer interaction through $p$ conjugated bridge results in substantial ground state donor-acceptor mixing and the appearance of a charge transfer band in the electronic absorption spectrum. Therefore, an electron density (ED) transfer occurs from the more aromatic part of the p conjugated system in the electron-donor side to electron-withdrawing part. The aromatic orbital components of the frontier molecular orbitals are shown in Fig. 4. The HOMOLUMO energy gap value are found at -0.19784 a.u in B3LYP/6$311+\mathrm{G}$. The calculated ground state energy of BI is $-0.21596 \mathrm{a} . \mathrm{u}$ in B3LYP method, which are responsible for the title compound. [36]

| Thermal correction to enthalpy | 0.191185 |
| Thermal correction to Gibbs free energy | 0.143726 |

## Molecular electrostatic potential

Molecular electrostatic potential (MEP) at a point in the space around a molecule gives an indication of the net electrostatic effect produced at that point by the total charge distribution (electron + nuclei) of the molecule and correlates with dipole moments, electronegativity, partial charges and chemical reactivity of the molecules. It provides a visual method to understand the relative polarity of the molecule. An electron density isosurface mapped with electrostatic potential surface depicts the size, shape, charge density and site of chemical reactivity of the molecules. The different values of the electrostatic potential represented by different colors; red represents the regions of the most negative electrostatic potential, blue represents the regions of the most positive electrostatic potential and green represents the region of zero potential. Potential increases in the order red < orange < yellow < green < blue. Such mapped electrostatic potential surface have been plotted for title molecule in B3LYP/6-311+G basis set using the computer software Gauss view. Projections of these surfaces along the molecular plane and a perpendicular plane are given in Fig. 5. This figure provides a visual representation of the chemically active sites and comparative reactivity of atoms [37].

Fig 5. DFT B3LYP/6-311+G calculated 3D molecular electrostatic potential of 1-Benzylimidazole Thermodynamic parameters

In addition to the vibrational assignments, several thermodynamic parameters, rotational constants, and dipole moment have been presented in Table 6. The self consistent field (SCF) energy,zero point vibrational energies (ZPVEs), rotational constants and entropy $\operatorname{Svib}(T)$ are calculated to the extent of accuracy and variations in the ZPVEs seem to be insignificant [38]. Dipole moment reflects the molecular charge distribution and is given as a vector in three dimensions. Therefore, it can be used as descriptor to depict the charge movement across the molecule. Direction of the dipole moment vector in a molecule depends on the centers of positive and negative charges. Dipole moments are strictly determined for neutral molecules. For charged systems, its value depends on the choice of origin and molecular orientation.

## Conclusion

The present investigation thoroughly analyzed the HOMOLUMO, NBO analyses, and the vibrational spectra, both infrared and Raman of BI molecule with B3LYP/6-31G and B3LYP/6$311+\mathrm{G}$ methods. All the vibrational bands observed in the FT-IR and FT-Raman spectra of the compound are assigned to the various modes of vibration and most of the modes have wavenumbers in the expected range. The complete vibrational assignments of wave numbers are made on the basis of potential
energy distribution (PED). The scaled B3LYP/6-311+G results are the best over the B3LYP/6-31G method. The molecular electrostatic potential surfaces (MEP) together with complete analysis of the vibrational spectra, both IR and Raman spectra help to identify the structural properties of the title molecule. The excellent agreement of the calculated and observed vibrational spectra reveals the advantages of higher basis set for quantum chemical calculations. NBO analysis provides an efficient method for studying inter and intra molecular interaction in molecular system. The stabilization energy has been calculated from second order perturbation theory. Natural Bond Orbital analysis shows the differences in interaction of energies are due to the substitution of $\mathrm{CH}_{2}$ group. Finally, the calculated HOMO and LUMO energies show that charge transfer occur in the molecule, which are responsible for the bioactive property of the biomedical compound BI
