Protein,
Amino acid,
Graph theory,
Matrices.

#### Abstract

In this paper we developed new matrices (angle matrix ,connection matrix and connection angle matrix) in addition to a set of matrices (adjacent matrix, incidence matrix) that previously used to introduce the mathematical representation of high-resolution protein structures an accurate representatin that facilitate analysis of its structures.

## Introduction

## Definition and background:-

- Abstract graphs: An abstract graphs G is a diagram consisting of a finite non empty set of the elements, called "vertices" denoted by V (G) together with a set of unordered pairs of these elements, called "edges" denoted by E (G). The set of vertices of the graph G is called "the vertex set of G" and the list of edges is called "the edge - list of G" [Gibbons, 1995; Giblin, 1977].
- Adjacency and incidence: let v and w be vertices of a graph. If $v$ and $w$ are joined by an edge $e$. then $v$ and $w$ are said to be adjacent. Moreover, $v$ and $w$ are said to be incident with $e$, and e is said to be incident with v and w [Wilson, 1972].
- The adjacency matrix: let G be a graph without loops, with nvertices labeled $1,2,3, \ldots$. $n$. The adjacency matrix $A(G)$ is the nxn matrix in which the entry in row $i$ and column $j$ is the length of edge in angstroms if the vertices $i$ and $j$ are joining and 0 otherwise. [Modification: Wilson, 1972].
- The incidence matrix: let $G$ be a graph without loops, with nvertices labeled $1,2,3, \ldots \mathrm{n}$ and m edges labeled $1,2,3, \ldots \ldots$, m . the incidence matrix $\mathrm{I}(\mathrm{G})$ is the $\mathrm{n} x \mathrm{~m}$ matrix in which the entry in row $i$ and column $j$ is 1 if vertex $i$ is incident with edge $j$ and 0 otherwise [Gross, 1987; Wilson, 1990].
- Angle matrix: let G be a graph without loops, with n -vertices labeled $1,2,3, \ldots \mathrm{n}$ and m edges labeled $1,2,3, \ldots$, m . the angle matrix $g(G)$ is the $m \times m$ matrix in which the entry in row $i$ and column $j$ is the angle in degrees if edge $i$ and $j$ are incident with the same vertex and 0 otherwise.(New matrix)
- Connection matrix: let g1 be a directed subgraph without loops, with n1-vertices labeled $1,2,3 . \ldots \mathrm{n} 1$ and g 2 be another directed subgraph without loops, with n2-vertices labeled $1,2,3$, $\ldots . ., \mathrm{n} 2$. The connection matrix $\mathrm{C}(\mathrm{g} 1, \mathrm{~g} 2)$ is the n 1 xn 2 matrix in which the entry in row $i$ and column $j$ is the length of edge in angstroms if the vertices i and j are joining and 0 otherwise. [New matrix].
- Connection Angle matrix: let g1 be a directed weighted subgraph without loops, with n1-vertices labeled $1,2,3 \ldots$ n1,
m1- edges labeled $1,2,3 \ldots \mathrm{~m} 1, \mathrm{~g} 2$ be another directed weighted subgraph without loops, with n2-vertices labeled $1,2,3 . \ldots$ n2, $\mathrm{m} 2-$ edges labeled $1,2,3 \ldots \mathrm{~m} 2$ and E is a directed connector between $\mathrm{g} 1, \mathrm{~g} 2$. the connection angle matrix $\mathrm{CL}(\mathrm{G})$ is the m 1 x E matrix or E x m 2 in which the entry in row i and column j is the angle in degrees if edge i and j are incident with the same vertex and 0 otherwise.(New matrix)

## Main results

Now we will represent the Mean values of Main-chain bond lengths and bond angles extracted from PROCHECK Operating Manual Appendix A Stereochemical parameters TABLE A. 1 (http://www.ebi.ac.uk/thornton srv/software/PROCHECK/manual/manappa.html) as observed in small molecules (Engh \& Huber, 1991) that derived from high-resolution protein structures using graph matrices (Figure 1).

## Definition

Representation of high-resolution protein structure backbone using a directed weighted graph ( G ) in consideration atoms as vertices and chemical bonds between atoms as edges in 2 steps.

## The First step:-

Representation of each amino acid residue backbone (except glycine and proline) as undirected weighted sub graph (g) all in protein primary structure as a directed weighted graph (G) using 2 matrices.
A (g) all =

| $\mathrm{N} \mathrm{C} \alpha \mathrm{C} O$ | N | $\mathrm{C} \alpha$ | C | O |
| :--- | :--- | :--- | :--- | :--- |
|  | 0 | 1.458 | 0 | 0 |
|  | 1.458 | 0 | 1.525 | 0 |
|  | 0 | 1.525 | 0 | 1.231 |
|  | 0 | 0 | 1.231 | 0 |

Where $\mathrm{N}, \mathrm{C} \alpha, \mathrm{C}, \mathrm{O}$ represent the vertices of subgraph ( g ) all and values in cells represent the length of edges in angstrom.
$I(g)_{\text {all }}=$
