DFT calculations.

#### Abstract

The FT-IR and FT-Raman spectra of P-Chloroaniline (PCA) have been recorded and analyzed. The optimized geometry, and harmonic vibrational wave numbers of PCA have been investigated with the help of B3LYP scaled quantum mechanical (SQM) method supplemented with $6-311++G^{* *}$ basis set. The infrared and Raman spectra were predicted theoretically from the calculated intensities. The observed and simulated spectra were found to be well comparable. In the investigation, we adopted density functional theory (DFT) combined with quantum chemical calculations to determine the first-order hyperpolarizability.

## Introduction

P-Chloroaniline (PCA) is an important building block used in the chemical industry for the production of pesticides, drugs, and dyestuffs. It is a precursor to the widely used antimicrobial and bacteriocide Chlorhexidine and is used in the manufacture of pesticides, including pyraclostrobin, anilofos, monolinuron and chlorphthalim. Some benzodiazepine drugs use PCA in their manufacture. The vibrational spectra of substituted aniline have been the subject of several investigations. Literature survey reveals that to the best of our knowledge, the results based on quantum chemical calculations, FT-IR and FT-Raman spectral analyses on PCA have no reports. Herein, we reported detailed interpretations of the infrared and Raman spectra based on the experimental and theoretical results, which are acceptable and supportable to each other. In the present work, we have attempted to interpret the vibrational spectra of PCA by using B3LYP level of theory throughout with the $6-311++\mathrm{G}^{* *}$ basis set implemented in the Gaussian 03 program suite.

## Methodology

## Experimental Details

The fine sample of PCA was obtained from Lancaster Chemical Company, UK and used as such for the spectral measurements. The FT-Raman spectrum of PCA was recorded using 1064 nm line of Nd:YAG laser as excitation wave length in the region $3500-100 \mathrm{~cm}^{-1}$ on thermo electron corporation model Nexus 670 spectrometer equipped with FT-Raman module accessory. The FT-IR spectrum of the title compound was recorded in the region $4000-400 \mathrm{~cm}^{-1}$ on Perkin Elmer Spectrophotometer in KBr pellet technique.

## Computational methods

Quantum chemical calculations were used for PCA to carry out the optimized geometry and vibrational wavenumbers with the 2003 version of the Gaussian suite of program using the Becke-3-Lee-Yang-Parr (B3LYP) [1,2] functional supplemented with standard $6-311++\mathrm{G}^{* *}$ basis set. The vibrational modes were assigned by means of visual inspection using the GAUSSVIEW program. The symmetry of the
molecule was also helpful in making vibrational assignments. The symmetries of the vibrational modes were determined by using standard procedure of decomposing the traces of the symmetry operations into irreducible representations. From the basic theory of Raman scattering Raman activities $\left(S_{i}\right)$ calculated by Gaussian 03 program have been converted to relative Raman intensities (Ii) using the following relationship:

$$
\begin{equation*}
I_{i}=\frac{f\left(\gamma_{o}-\gamma_{i}\right)^{4} s_{i}}{\gamma_{i}\left[1-\exp \left(\frac{-h c \gamma_{i}}{K T}\right)\right]} \tag{1}
\end{equation*}
$$

where $\gamma_{0}$ is the exciting wave number (in $\mathrm{cm}^{-1}$ units), $\gamma_{i}$ is the vibrational wave number of the in $i t h$ normal mode, $h, c$, and $k$ are universal constant and $f$ is the suitably chosen common scaling factor for all the peak intensities.

The analysis for the vibrational modes of PCA was presented in some detail in order to better describe the basis for the assignments. All the parameters were allowed to relax and all the calculations converged to an optimized geometry which corresponds to a true energy minimum, as revealed by the lack of imaginary values with wavenumber calculations. The Cartesian representation of the theoretical force constant has been computed at the fully optimized geometry by assuming the molecule belongs to $\mathrm{C}_{\mathrm{s}}$ point group symmetry. The transformation force field from Cartesian to internal local symmetry coordinates, scaling the subsequent normal coordinate analysis (NCA), calculation of Potential Energy Distribution (PED) were done on a PC with the version V7.0-G77 of the MOLVIB program written by Sundius [3-10].

The optimized molecular structure of PCA was shown in Fig.1. The global minimum energy obtained by the DFT structure optimization was presented in Table 1. The optimized geometrical parameters obtained by the large basis set calculation were presented in Table 2. A detailed description of vibrational modes can be given by means of normal coordinate analysis. For this purpose, a full set of 49 standard

## Tele:

E-mail addresses: photonic_ss@rediffmail.com
internal coordinates containing 13 redundancies were defined as given in Table. 3. From these, a non-redundant set of local symmetry coordinates were constructed by suitable linear combinations of internal coordinates following the recommendation of Pulay et al [11] and they are presented in Table .4. The theoretically calculated SQM force fields were transformed to this later set of vibrational coordinates and used in all subsequent calculations.

## Essentials of nonlinear optics related to $\boldsymbol{\beta}$

The nonlinear response of an isolated molecule in an electric field $\mathrm{E}_{\mathrm{i}}(\omega)$ can be represented as a Taylor expansion of the total dipole moment $\mu_{\mathrm{t}}$ induced by the field:

$$
\mu_{\mathrm{t}}=\mu_{0}+\alpha_{\mathrm{ij}} \mathrm{E}_{\mathrm{i}}+\beta_{\mathrm{ijk}} \mathrm{E}_{\mathrm{i}} \mathrm{E}_{\mathrm{j}}+\ldots \ldots
$$

Where $\alpha$ is linear polarizability, $\mu_{0}$ the permanent dipole moment and $\beta_{\mathrm{ijk}}$ are the first-order hyperpolarizability tensor components.

The components of first-order hyperpolarizability can be determined using the relation

$$
\beta_{\mathrm{i}}=\beta_{\mathrm{iii}}+\frac{1}{3} \sum_{i \neq j}\left(\beta_{i j j}+\beta_{j i j}+\beta_{j j i}\right)
$$

Using the $\mathrm{x}, \mathrm{y}$ and z components the magnitude of the total static dipole moment $(\mu)$, isotropic polarizability ( $\alpha_{0}$ ), first-order hyperpolarizability ( $\beta_{\text {total }}$ ) tensor, can be calculated by the following equations:

$$
\begin{aligned}
& \mu_{1}^{0}=\left(\mu_{\mathrm{x}}^{2}+\mu_{\mathrm{y}}^{2}+\mu_{\mathrm{z}}^{2}\right)^{1 / 2} \\
& \beta_{\mathrm{tot}}=\left(\beta_{\mathrm{x}}^{2}+\beta_{\mathrm{y}}{ }^{2}+\beta_{\mathrm{z}}^{2}\right)^{1 / 2}
\end{aligned}
$$

The complete equation for calculating the first-order hyperpolarizability from GAUSSIAN 03 W output is given as follows [12]:

$$
\beta_{\mathrm{tot}}=\left[\left(\beta_{\mathrm{xxx}}+\beta_{\mathrm{xyy}}+\beta_{\mathrm{xzz}}\right)^{2}+\left(\beta_{\mathrm{yyy}}+\beta_{\mathrm{yzz}}+\beta_{\mathrm{yxx}}\right)^{2}+\left(\beta_{z z z}+\beta_{z x x}+\beta_{z y y}\right)^{2}\right]
$$

The $\beta$ components of GAUSSIAN 98W output are reported in atomic units, the calculated values have to be converted into electrostatic units ( $1 \mathrm{a} . \mathrm{u}=8.3693 \times 10^{-33} \mathrm{esu}$ ).

Before calculating the hyperpolarizability for the investigated compound, the optimization has been carried out in the UHF (unrestricted open-shell Hartree-Fock) level. Molecular geometries were fully optimized by Berny's optimization algorithm using redundant internal coordinates. All optimized structures were confirmed to be minimum energy conformations. An optimization is complete when it has converged. i.e., when it has reached a minimum on the potential energy surface, thereby predicting the equilibrium structures of the molecules.

This criterion is very important in geometry optimization. The inclusion of $d$ polarization and double zeta function in the split valence basis set is expected to produce a marked improvement in the calculated geometry.

At the optimized structure, no imaginary frequency modes were obtained proving that a true minimum on the potential energy surface was found. The electric dipole moment and dispersion free first-order hyperpolarizibility were calculated using finite field method. The finite field method offers a straight forward approach to the calculation of hyperpolarizabilities. All the calculations were carried out at the DFT level using the three-parameter hybrid density functional B3LYP and a 3-21 G (d, p) basis set.

## Result and Discussion

## Structure and Symmetry

The optimized structural parameters and global minimum energy of PCA were calculated by $C_{s}$ point group symmetry with B3LYP/6-311++G** level. In accordance with the atom numbering scheme is given in Fig. 1. The global minimum energy of PCA is -747.19885835 hartrees. The optimized structure of the title compound was compared with other similar systems for which the crystal structures have been solved. From the theoretical values we can find that most of the optimized bond lengths are slightly longer and shorter than experimental values. The computed bond length and bond angles show satisfactory agreement with experimental observation.

## Vibrational assignments

The 36 normal modes of PCA are distributed among the symmetry species as $\Gamma_{3 \mathrm{~N}-6}=25 A^{\prime}$ (in-plane) $+11 A^{\prime \prime}$ (out-ofplane) by assuming $C_{s}$ point group symmetry. The detailed vibrational assignments of fundamental modes of PCA along with observed and calculated frequencies, IR intensities, Raman scattering activities and normal mode descriptions have been reported in Table 5. The observed and simulated FT-IR and FTRaman spectra of PCA are produced in a common frequency scales in Fig. 2 \& Fig. 3.

Root mean square (RMS) values of frequencies were obtained in the study using the following expression,

$$
\mathrm{RMS}=\sqrt{\frac{1}{\mathrm{n}-1} \sum_{\mathrm{i}}^{\mathrm{n}}\left(\mathrm{u}_{\mathrm{i}}^{\text {calc }}-\mathrm{u}_{\mathrm{i}}^{\exp }\right)^{2}}
$$

The RMS error of the observed and calculated frequencies (unscaled / B3LYP/6-311+G**) of PCA was found to be 103 $\mathrm{cm}^{-1}$. This is quite obvious; since the frequencies calculated on the basis of quantum mechanical force fields usually differ appreciably from observed frequencies. This is partly due to the neglect of anharmonicity and partly due to the approximate nature of the quantum mechanical methods. In order to reduce the overall deviation between the unscaled and observed fundamental frequencies, scale factors were applied in the normal coordinate analysis and the subsequent least square fit refinement algorithm resulted into a very close agreement between the observed fundamentals and the scaled frequencies. Refinement of the scaling factors applied in this study achieved a weighted mean deviation of $9.32 \mathrm{~cm}^{-1}$ between the experimental and scaled frequencies of the title compound. It is
convenient to discuss the vibrational spectra of PCA in terms of characteristic spectral region as describe below.

Fig. 3. FT-Raman spectra of PCA
(a) Observed (b) Calculated with B3LYP/6-311+G**

## $\mathbf{C}-\mathbf{H}$ vibration

The presence of hetro-aromatic-type structure is best recognized by the presence of $\mathrm{C}-\mathrm{H}$ stretching vibrations [13] near $3030 \mathrm{~cm}^{-1}$. In this region, the absorption bands are little affected by the substitutional patterns and the presence of conjunction with double bonds of the ring. In PCA the band were observed at $3037 \mathrm{~cm}^{-1}$ and $3061 \mathrm{~cm}^{-1}$ in FTIR \& FT Raman respectively.
$\mathbf{C}-\mathbf{C l}$ vibration
In present investigation, The $\mathrm{C}-\mathrm{Cl}$ stretching frequency is generally observed in the region $800-600 \mathrm{~cm}^{-1}$ depending on the configuration and conformation of the compound [14]. Based on this, the FTIR and FT-Raman bands observed at 831,691,640 and $819,636 \mathrm{~cm}^{-1}$ has been assigned to $\mathrm{C}-\mathrm{Cl}$ stretching modes show strong mixing with several planar modes. However, the planar $\mathrm{C}-\mathrm{Cl}$ bending modes appear to be relatively pure modes. The $\mathrm{C}-\mathrm{Cl}$ out of plane bending modes were identified at 286 $\mathrm{cm}^{-1}$ and $327 \mathrm{~cm}^{-1}$ for IR and Raman, respectively.

## $\mathbf{C}-\mathbf{N}$ vibrations

The identification of $\mathrm{C}-\mathrm{N}$ stretching frequency is a very difficult task, since the mixing of bands are possible in this region. Hence the FT-IR bands observed at 1334, 1369, 1428, $1554 \mathrm{~cm}^{-1}$ and the Raman bands at $1597,1617 \mathrm{~cm}^{-1}$ in PCA are assigned to $\mathrm{C}-\mathrm{N}$ stretching modes of vibrations. These assignments are made in accordance with the assignments proposed by Roy [15].

## $\mathbf{N}-\mathbf{H}$ vibrations

In all the heterocyclic compounds, the $\mathrm{N}-\mathrm{H}$ stretching vibration [16] occur in the region $3500-3000 \mathrm{~cm}^{-1}$. Hence the FT-IR band observed at $3037 \mathrm{~cm}^{-1}$ and Raman band at 3061 $\mathrm{cm}^{-1}$ in PCA have been designated to $\mathrm{N}-\mathrm{H}$ stretching modes of vibrations.

## C-C vibrations

The bands between 1400 and $1650 \mathrm{~cm}^{-1}$ in benzene derivatives are assigned to $\mathrm{C}-\mathrm{C}$ stretching modes [17]. Accordingly in the present study, the carbon-carbon vibrations are observed in PCA at $1441 \mathrm{~cm}^{-1}$ in the FT-IR spectrum and $1478 \mathrm{~cm}^{-1}$ in the FT-Raman.

## Ring vibrations

Many ring modes are affected by the substitutions in the ring of PCA. In the present study the bands identified at 1039 , $843,704,418,408$ and $286 \mathrm{~cm}^{-1}$ for PCA have been designated to ring in-plane and out-of-plane bending modes, respectively by
careful consideration of their quantitative descriptions. A small change in frequencies observed for these modes are mainly due to the presence of Amino group in PCA and from different extents of mixing between ring and constituent group vibrations.

## Hyperpolarizability calculations

The first-order hyperpolarizibility $\left(\beta_{\mathrm{ijk}}\right)$ of the novel molecular system of PNBC is calculated using 3-21 G (d,p) basis set based on finite field approach. Hyperpolarizibility is a third rank tensor that can be described by a $3 \times 3 \times 3$ matrix. It strongly depends on the method and basis set used. The 27 components of 3D matrix can be reduced to 10 components due to Kleinman [18] symmetry. The calculated first-order hyperpolarizability ( $\beta_{\text {total }}$ ) of PCA is $0.251551 \times 10^{-30} \mathrm{esu}$, which value is higher than that of urea $\left(0.1947 \times 10^{-30} \mathrm{esu}\right)$. The calculated dipole moment ( $\mu$ ) and first-order hyperpolarizibility $(\beta)$ are shown in Table 6. The theoretical calculation seems to be more helpful in determination of particular components of $\beta$ tensor than in establishing the real values of $\beta$. Domination of particular components indicates on a substantial delocalization of charges in those directions. It is noticed that in $\beta_{\mathrm{zxx}}$ (which is the principal dipole moment axis and it is parallel to the charge transfer axis) direction, the biggest values of hyperpolarizability are noticed and subsequently delocalization of electron cloud is more in that direction.

[^0]The higher dipole moment values are associated, in general, with even larger projection of $\beta_{\text {total }}$ quantities. The electric dipoles may enhance, oppose or at least bring the dipoles out of the required net alignment necessary for NLO properties such as $\beta_{\text {total }}$ values. The connection between the electric dipole moments of an organic molecule having donor-acceptor substituent and first hyperpolarizability is widely recognized in the literature [19]. The maximum $\beta$ was due to the behavior of non-zero $\mu$ value. One of the conclusions obtained from this work is that non-zero $\mu$ value may enable the finding of a non-zero $\beta$ value. Of course Hartee-Fock calculations depend on the mathematical method and basis set used for a polyatomic molecule.

## Table 6. The dipole moment ( $\mu$ ) and first-order hyperpolarizibility ( $\beta$ ) of PCA derived from DFT calculations

| $\beta_{x x x}$ | -0.04442 |
| :---: | :---: |
| $\beta_{\text {xxy }}$ | -0.08363 |
| $\beta_{\text {xyy }}$ | -0.15544 |
| $\beta_{\text {yyy }}$ | -0.00621 |
| $\beta_{z x x}$ | 0.125724 |
| $\beta_{\mathrm{xyz}}$ | 0.05038 |
| $\beta_{\text {zyy }}$ | -0.08832 |
| $\beta_{\text {xzz }}$ | -0.01715 |
| $\beta_{y z z}$ | 0.097021 |
| $\beta_{z z z}$ | -0.16441 |
| $\beta_{\text {total }}$ | 0.251551 |
| $\mu_{\mathrm{x}}$ | 0.975496967 |
| $\mu_{y}$ | $8.70489 \mathrm{E}-09$ |
| $\mu_{\mathrm{z}}$ | 0.331536658 |
| $\mu$ | 1.143255717 |

Dipole moment ( $\mu$ ) in Debye, hyperpolarizibility $\beta(-2 \omega ; \omega, \omega) 10^{-30}$ esu.

## Conclusions

The vibrational properties of P-Chloroaniline (PCA) have been investigated by FT IR and FT-Raman spectroscopies and were performed on the basis of DFT-B3LYP calculations at 6$311+\mathrm{G}^{* *}$ basis set level. The energy of the title compound has been calculated using the above mentioned basis sets. On the basis of the comparison between calculated and observed results, assignments of fundamental vibrational modes were examined using scaling procedure and found to be unambiguous. The simulated and observed IR and Raman spectra agree well with the better frequency fit and intensities. The calculated first-order
hyperpolarizability ( $\beta_{\text {total }}$ ) of PCA is $0.251551 \times 10^{-30}$ esu, which value is higher than that of urea $\left(0.1947 \times 10^{-30} \mathrm{esu}\right)$.
